

# Disjunctions for Hash Proof Systems: New Constructions and Applications

Michel Abdalla, Fabrice Benhamouda, and David Pointcheval

ENS, CNRS, INRIA, and PSL

October 2, 2015

**Abstract.** Hash Proof Systems were first introduced by Cramer and Shoup (Eurocrypt’02) as a tool to construct efficient chosen-ciphertext-secure encryption schemes. Since then, they have found many other applications, including password authenticated key exchange, oblivious transfer, and zero-knowledge arguments. One of the aspects that makes hash proof systems so interesting and powerful is that they can be seen as implicit proofs of membership for certain languages. As a result, by extending the family of languages that they can handle, one often obtains new applications or new ways to understand existing schemes. In this paper, we show how to construct hash proof systems for the disjunction of languages defined generically over cyclic, bilinear, and multilinear groups. Among other applications, this enables us to construct the most efficient one-time simulation-sound (quasi-adaptive) non-interactive zero-knowledge arguments for linear languages over cyclic groups, the first one-round group password-authenticated key exchange without random oracles, the most efficient threshold structure-preserving chosen-ciphertext-secure encryption scheme, and the most efficient one-round password authenticated key exchange in the UC framework.

**Keywords.** Hash Proof System, Non-Interactive Zero-Knowledge Proof, Group Password Authenticated Key Exchange, Threshold Encryption, Linearly Homomorphic Signature, Structure Preserving Primitive.

## 1 Introduction

Hash Proof Systems or Smooth Projective Hash Functions (SPHF), which can be seen as a kind of implicit designated-verifier proofs of membership [ACP09, BPV12], were originally introduced by Cramer and Shoup [CS02] as a way to build efficient chosen-ciphertext-secure (IND-CCA) encryption schemes. Informally speaking, SPHF are families of pairs of functions (Hash, ProjHash) defined on a language  $\mathcal{L} \subset \mathcal{X}$ . These functions are indexed by a pair of associated keys (hk, hp), where the hashing key hk and the projection key hp can be seen as the private and public keys, respectively. When computed on a word  $C \in \mathcal{L}$ , both functions should lead to the same result: Hash(hk,  $\mathcal{L}$ ,  $C$ ) with the hashing key and ProjHash(hp,  $\mathcal{L}$ ,  $C$ ,  $w$ ) with the projection key and a witness  $w$  that  $C \in \mathcal{L}$ . Of course, if  $C \notin \mathcal{L}$ , such a witness does not exist, and the smoothness property states that Hash(hk,  $\mathcal{L}$ ,  $C$ ) is independent of hp. As a consequence, the value Hash(hk,  $\mathcal{L}$ ,  $C$ ) cannot be guessed even with the knowledge of hp.

Since their introduction, SPHF have been used in various applications, including Password Authenticated Key Exchange (PAKE) [KOY01, GL03, KV11], Oblivious Transfer [Kal05, ABB<sup>+</sup>13], One-Time Relatively-Sound Non-Interactive Zero-Knowledge Arguments [JR12], Zero-Knowledge Arguments [BBC<sup>+</sup>13], and Trapdoor Smooth Projective Hash Functions (TSPHF) [BBC<sup>+</sup>13]. An SPHF for a language  $\mathcal{L}$  also directly leads to a witness encryption scheme [GGSW13] for the same language  $\mathcal{L}$ : encrypting a message  $m$  for a word  $C$  consists in generating an hashing key hk and a projection key hp and outputting hp together with  $m$  masked with the hash value Hash(hk,  $\mathcal{L}$ ,  $C$ ) of  $C$  under hk. If we know a witness  $w$  for  $C$ , we can compute this hash value from hp, while if  $C \notin \mathcal{L}$ , this hash value statistically masks the message.

As explained in [BBC<sup>+</sup>13], several variants of SPHF have been proposed over the years, depending on whether the projection key hp is allowed to depend on  $C$  and whether the smoothness holds even when  $C$  is chosen after having seen hp. For witness encryption schemes,

for example, the weakest notion ( $\text{hp}$  depends on  $C$ ) is sufficient, while for public-key encryption schemes and one-round PAKE, the strongest notion ( $\text{hp}$  does not depend on  $C$  and  $C$  may be chosen after  $\text{hp}$  in the smoothness property) is required. In this article, we focus on the strongest notion of SPHF, also called KV-SPHF in [BBC<sup>+</sup>13], since it has more applications. However, most parts of the paper could be adapted to use the weaker GL-SPHF notion.

**Expressiveness of SPHFs.** Due to the wide range of applications of SPHFs, one may wonder what kind of languages can be handled by SPHFs. First, since SPHF implies statistical witness encryption, it is important to remark that it is impossible to construct SPHF for any NP language, unless the polynomial hierarchy collapses [GGSW13]. Nevertheless, as the many different applications show, the class of languages supported by SPHFs can be very rich.

*Diverse Groups and Diverse Vector Spaces.* In [CS02], Cramer and Shoup showed that SPHFs can handle any language based on what they call a diverse group. Most, if not all, constructions of SPHF are based on diverse groups. However, in the context of languages over cyclic groups, bilinear groups or even multilinear groups, diverse groups may appear slightly too generic. That is why, in [BBC<sup>+</sup>13], Benhamouda et al. introduced a generic framework (later called *diverse vector space*) encompassing most known SPHFs based over these kinds of groups. It can be seen as particular diverse groups with more mathematical structure, namely using vector spaces instead of groups. This idea is actually already present in Section 7.4.1 of the full version of [CS02]. In this article, we are mainly interested on SPHFs based on diverse vector spaces.

*Operations on SPHFs.* In order to enrich the class of languages that can be handled by SPHFs, Abdalla, Chevalier, and Pointcheval [ACP09] showed how to build SPHFs for languages that can be described in terms of disjunctions and conjunctions of simpler languages for which SPHFs are known to exist. Let  $\mathcal{L}_1$  and  $\mathcal{L}_2$  be two such languages. In the particular case of conjunctions, when given SPHFs for  $\mathcal{L}_1$  and  $\mathcal{L}_2$ , they showed how to build an SPHF for the conjunction  $\mathcal{L} = \mathcal{L}_1 \times \mathcal{L}_2$ , so that a word  $C = (C_1, C_2) \in \mathcal{L}$  if and only if  $C_1 \in \mathcal{L}_1$  and  $C_2 \in \mathcal{L}_2$ . Note that this definition is a generalization of the “classical” conjunction:  $C_1 \in \mathcal{L}$  if and only if  $C_1 \in \mathcal{L}_1$  and  $C_1 \in \mathcal{L}_2$ , which we can get by setting  $C_1 = C_2$ .

In the case of disjunctions, when given SPHFs for  $\mathcal{L}_1$  and  $\mathcal{L}_2$ , Abdalla et al. showed how to build an SPHF for language  $\mathcal{L} = (\mathcal{L}_1 \times \mathcal{X}_2) \cup (\mathcal{X}_1 \times \mathcal{L}_2)$ , so that  $C = (C_1, C_2) \in \mathcal{L}$  if and only if  $C_1 \in \mathcal{L}_1$  or  $C_2 \in \mathcal{L}_2$ . In particular, a witness for  $C = (C_1, C_2) \in \mathcal{L}$  can be either a witness  $w_1$  for  $C_1 \in \mathcal{L}_1$  or a witness  $w_2$  for  $C_2 \in \mathcal{L}_2$ . As for conjunctions, by setting  $C_1 = C_2$ , one gets the “classical” disjunction:  $C = (C_1, C_1) \in \mathcal{L}$  if and only if  $C_1 \in \mathcal{L}_1$  or  $C_1 \in \mathcal{L}_2$ .

Unfortunately, while the conjunction of two strong SPHFs in [ACP09] yields a strong SPHF, the same is not true for disjunctions, where the projection key  $\text{hp}$  necessarily depends on  $C$ . And this greatly limits its applications<sup>1</sup>.

## 1.1 Results

**Disjunction of SPHFs.** Our first main result is to show how to construct the disjunction of two SPHFs for two languages based on diverse vector spaces. Essentially, the only requirement for the construction is that it is possible to compute a pairing between an element of the first language  $\mathcal{L}_1$  and an element of the second language  $\mathcal{L}_2$ . Concretely, if we have a bilinear map  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  where  $\mathbb{G}_1$ ,  $\mathbb{G}_2$  and  $\mathbb{G}_T$  are cyclic groups of some prime order  $p$  (we say that  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$  is a bilinear group), and if  $\mathcal{L}_1$  is defined over  $\mathbb{G}_1$  and  $\mathcal{L}_2$  over  $\mathbb{G}_2$ , then our construction provides an SPHF for the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$ . Furthermore, this disjunction can be repeated multiple times, if multilinear maps are available. The only limitation is that the

<sup>1</sup> A reader familiar with [Gro06] may wonder why the methods in [Gro06] cannot be applied to provide a form of disjunction, given that SPHFs exist for languages of quadratic pairing equations over commitments [BBC<sup>+</sup>13]. Unfortunately, this technique would not yield a real SPHF, since additional commitments would be required.

complexity of our constructions grows exponentially with the number of repetitions, therefore limiting the total number of disjunctions that we can compute.

**Application: Constant-Size NIZK and One-Time Simulation-Sound NIZK.** First, we show how to use disjunctions of SPHF to create efficient *non-interactive zero-knowledge arguments* (NIZK) and even *one-time simulation-sound NIZK*, i.e., NIZK in which a dishonest (polynomial-time) prover cannot produce a valid proof of a false statement, even when seeing one simulated proof on a statement of its choice (which may be false). The proof size consists of only two group elements, even for the one-time simulation-sound version, assuming the language we are interested in can be handled by an SPHF over some group  $\mathbb{G}_1$ , where  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T)$  is an asymmetric bilinear group, and assuming DDH is hard in  $\mathbb{G}_2$ . The languages handled roughly consist of languages defined by “linear” equations over  $\mathbb{G}_1$ , such as the DDH language, the language of valid Cramer-Shoup [CS98] ciphertexts and many other useful languages as shown in [BBC<sup>+</sup>13, JR13].

Our NIZK is slightly different from a usual NIZK, since the common reference string depends on the language. Jutla and Roy called them quasi-adaptive NIZK in [JR13], and showed that they can replace NIZK in several applications.

Our one-time simulation-sound NIZK yields a very efficient structure-preserving threshold IND-CCA encryption scheme, with the shortest ciphertext size so far. Threshold means the decryption key can be shared between parties and a ciphertext can be decrypted if and only if enough parties provide a partial decryption of it using their key share, while structure-preserving means it can be used in particular with Groth-Sahai NIZK [GS08] or our new NIZK construction. In addition, this new encryption can be used in the one-round password authenticated key exchange (PAKE) scheme in the UC model in [BBC<sup>+</sup>13] to obtain an improvement of up to 30% in the communication complexity, under the same assumptions.

**Other Applications.** Another important application is the first *one-round group password authenticated key exchange* (GPAKE) with  $n$  players, assuming the existence of a  $(n-1)$ -multilinear map and the hardness of the  $n$ -linear assumption  $n$ -Lin without random oracles<sup>2</sup>. This was an open problem. We remark, however, that our construction only works for small values of  $n$  since the overall complexity of the protocol and the gap in the security reduction grows exponentially in  $n$ . We note, however, that the tripartite PAKE which only requires pairings is reasonably efficient since it consists of flows with 61 group elements for each user (5 for the Cramer-Shoup ciphertext and 56 for the projection key).

A second application is a new construction for TSPHF, which supports slightly more languages than the original one, but which is slightly less efficient. A TSPHF (Trapdoor Smooth Projective Hash Function [BBC<sup>+</sup>13]) is a variant of an SPHF with a full-fledged zero-knowledge flavor: there exists a trapdoor for computing the hash value of any word  $C \in \mathcal{X}$  when only given  $C$  and the projection key  $hp$ .

Finally, the unforgeability of the one-time linearly homomorphic structure-preserving signature scheme of Libert et al. [LPJY13] can be explained by the smoothness of some underlying SPHF, which can be seen as the disjunction of two SPHFs. This new way of seeing their signature scheme directly shows how to extend it to other assumptions, such as SXDH,  $\kappa$ -Lin, or even any MDDH assumption [EHK<sup>+</sup>13] secure in bilinear groups.

**Pseudo-Random Projective Hash Functions (PrPHFs) and More Efficient Applications.** For our NIZK and our new TSPHF, the construction essentially consists in the disjunction of an SPHF for the language in which we are interested, and another SPHF for a language which is used to provide extra features (zero-knowledge and “public verifiability” for our NIZK and

<sup>2</sup> At the time the first version of this paper was made public, the multilinear map construction by Coron et al. [CLT13] seemed to be a plausible candidate. However, as recently shown by Cheon et al. [CHL<sup>+</sup>14], this is no longer the case. Unfortunately, no current candidate multilinear map construction is known to work for our framework for  $n \geq 3$ .

trapdoor for our TSPHF). This second language  $\mathcal{L}_2$  is supposed to be a hard subset membership one, i.e., it is hard to distinguish a random word  $C_2 \in \mathcal{L}_2$  from a random word  $C_2 \in \mathcal{X}_2 \setminus \mathcal{L}_2$ .

To get more efficient applications, we introduce the notion of pseudo-random projective hash functions (PrPHFs) which are particular SPHFs over trivial languages, i.e., languages  $\mathcal{L} = \mathcal{X}$ , where all words are in the language. Of course, smoothness becomes trivial, in this case. That is why PrPHFs are supposed to have another property called *pseudo-randomness*, which ensures that if the parameters of the language  $\mathcal{L}$  and the word  $C$  are chosen at random, given a projection key  $\text{hp}$  (and no witness for  $C$ ), the hash value  $H$  of  $C$  appears random.

We then show that we can replace the second hard subset membership language in our NIZK and our TSPHF by a trivial language with a PrPHF, assuming a certain property over the first language  $\mathcal{L}_1$  (which is almost always verified). This conversion yields slightly shorter proofs (for our NIZK and our one-time simulation-sound NIZK) or slightly shorter projection keys (for our TSPHF).

**Related Work.** Until now, the most efficient NIZK for similar languages was the one of Jutla and Roy [JR14], and the most efficient *one-time* simulation-sound NIZK was the *unbounded* simulation-sound NIZK of Libert et al. [LPJY14]. Even though all these constructions have constant-size proofs, our second NIZK is slightly more efficient for  $\kappa$ -linear assumptions, with  $\kappa \geq 2$ , while our one-time simulation-sound NIZK is about ten times shorter. Moreover, our construction might be simpler to understand due to its modularity. We provide a detailed comparison in Section 7.3.

## 1.2 Organization

In the next section, we give the high level intuition for all our constructions and their applications. Then, after recalling some preliminaries in Section 3, we give the details of our construction of disjunctions of SPHFs in Section 4, which is one of our main contributions. We then show how to build efficient NIZK and one-time simulation-sound NIZK from it in Section 5. After that, we introduce the notion of PrPHF in Section 6 and show in Section 7 how this can improve some of our previous applications. These last two sections are much more technical: although the underlying ideas are similar to the ones in previous sections, the proofs are more complex. Due to lack of space, details of our two other applications, namely one-round GPAKE and TSPHF, are presented in Appendix D, but an overview is available in Section 2.3.

## 2 Overview of Our Constructions

### 2.1 Disjunction of Languages

**Intuition.** From a very high point of view, the generic framework [BBC<sup>+</sup>13] enables us to construct an SPHF for any language  $\mathcal{L}$  which is a subspace of the vector space of all words  $\mathcal{X}$ .

It is therefore possible to do the conjunction of two languages  $\mathcal{L}_1$  and  $\mathcal{L}_2$  supported by this generic framework by remarking that  $\mathcal{L}_1 \times \mathcal{L}_2$  is a subspace of the vector space  $\mathcal{X}_1 \times \mathcal{X}_2$ . This construction of conjunctions is an “algebraic” version of the conjunction proposed in [ACP09].

Unfortunately, the same approach cannot be directly applied to the case of disjunctions, because  $(\mathcal{L}_1 \times \mathcal{X}_2) \cup (\mathcal{X}_1 \times \mathcal{L}_2)$  is not a subspace of  $\mathcal{X}_1 \times \mathcal{X}_2$ , and the subspace generated by the former union of sets is  $\mathcal{X}_1 \times \mathcal{X}_2$ . In this article, we solve this issue by observing that, instead of using  $\mathcal{X} = \mathcal{X}_1 \times \mathcal{X}_2$ , we can consider the tensor product of  $\mathcal{X}_1$  and  $\mathcal{X}_2$ :  $\mathcal{X} = \mathcal{X}_1 \otimes \mathcal{X}_2$ . Then the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$  can be seen as the subspace  $\mathcal{L}$  of  $\mathcal{X}$  generated by:  $\mathcal{L}_1 \otimes \mathcal{X}_2$  and  $\mathcal{X}_1 \otimes \mathcal{L}_2$ . Notice that  $(\mathcal{L}_1 \otimes \mathcal{X}_2) \cup (\mathcal{X}_1 \otimes \mathcal{L}_2)$  is not a subspace and so  $\mathcal{L}$  is much larger than this union of sets. But we can prove that if  $C_1 \otimes C_2 \in \mathcal{L}$ , then  $C_1 \in \mathcal{L}_1$  or  $C_2 \in \mathcal{L}_2$ .

Before providing more details about these constructions, let us first briefly recall the main ideas of the generic framework for constructing SPHFs.

**Generic Framework for SPHF.** The generic framework for SPHFs in [BBC<sup>+</sup>13] uses a common formalization for cyclic groups, bilinear groups, and even multilinear groups<sup>3</sup> (of prime order  $p$ ), called graded rings<sup>4</sup>.

Basically, graded rings enable us to use a ring structure over these groups: the addition and the multiplication of two elements  $u$  and  $v$ , denoted  $u + v$  and  $u \bullet v$ , respectively, correspond to the addition and the multiplication of their discrete logarithms. For example, if  $g$  is a generator of a cyclic group  $\mathbb{G}$ , and  $a$  and  $b$  are two scalars in  $\mathbb{Z}_p$ ,  $a + b = a + b$ ,  $a \bullet b = a \cdot b$  (because the “discrete logarithm” of a scalar is the scalar itself),  $g^a + g^b = g^{a+b}$ , and  $g^a \bullet g^b = g^{a \cdot b}$ , with  $g_T$  a generator of another cyclic group  $\mathbb{G}_T$  of order  $p$ .

Of course, computing  $g^a \bullet g^b = g^{a \cdot b}$  requires a bilinear map  $e : \mathbb{G} \times \mathbb{G} \rightarrow \mathbb{G}_T$ , if the discrete logarithms of  $g^a$  and  $g^b$  are not known. And if such a bilinear map exists, we can compute  $g^a \bullet g^b$  as  $e(g^a, g^b)$ . For a similar reason, the multiplication of three group elements via  $\bullet$  would require a trilinear map. Therefore, graded rings can be seen as the ring  $\mathbb{Z}_p$  with some limitations on the multiplication. Here, to avoid technicalities, the group of each element is implicit, and we suppose that above constraints on the multiplications are satisfied. Formal details are left to the following sections.

From a high level point of view, in this framework, we suppose there exists a map  $\theta$  from the set of words  $\mathcal{X}$  to a vector space  $\hat{\mathcal{X}}$  of dimension  $n$ , together with a subspace  $\hat{\mathcal{L}}$  of  $\hat{\mathcal{X}}$ , generated by a family of vectors  $(\mathbf{F}_i)_{i=1}^k$ , such that  $C \in \mathcal{L}$  if and only if  $\theta(C) \in \hat{\mathcal{L}}$ . When the function  $\theta$  is clear from context, we often write  $\hat{C} := \theta(C)$ .

A witness for a word  $C \in \mathcal{L}$  is a vector  $\boldsymbol{\lambda} = (\lambda_i)_{i=1}^k$  so that  $\hat{C} = \theta(C) = \sum_{i=1}^k \lambda_i \bullet \mathbf{F}_i$ . In other words, it consists of the coefficients of a linear combination of  $(\mathbf{F}_i)_{i=1}^k$  equal to  $\hat{C}$ .

Then, a hashing key  $\text{hk}$  is just a random linear form  $\text{hk} := \alpha \in \hat{\mathcal{X}}^*$  ( $\hat{\mathcal{X}}^*$  being the dual vector space of  $\hat{\mathcal{X}}$ , i.e., the vector space of linear maps from  $\hat{\mathcal{X}}$  to  $\mathbb{Z}_p$ ), and the associated projection key is the vector of its values on  $\mathbf{F}_1, \dots, \mathbf{F}_k$ :

$$\text{hp} := \boldsymbol{\gamma} = (\gamma_i)_{i=1}^k = (\alpha(\mathbf{F}_i))_{i=1}^k.$$

The hash value of a word  $C$  is then  $H := \alpha(\hat{C})$ . If  $\boldsymbol{\lambda}$  is a witness for  $C \in \mathcal{L}$ , then the latter can also be computed as:

$$H = \alpha(\hat{C}) = \alpha\left(\sum_{i=1}^k \lambda_i \bullet \mathbf{F}_i\right) = \sum_{i=1}^k \lambda_i \bullet \alpha(\mathbf{F}_i) = \sum_{i=1}^k \lambda_i \bullet \gamma_i,$$

which only depends on the witness  $\boldsymbol{\lambda}$  and the projection key  $\text{hp}$ . The smoothness comes from the fact that, if  $C \notin \mathcal{L}$ , then  $\hat{C} \notin \hat{\mathcal{L}}$  and  $\hat{C}$  is linearly independent from  $(\mathbf{F}_i)_{i=1}^k$ . Hence,  $\alpha(\hat{C})$  looks random even given  $\text{hp} = (\alpha(\mathbf{F}_i))_{i=1}^k$ .

For a reader familiar with [CS02], the generic framework is similar to a diverse group, but with more structure: a vector space instead of a simple group. When  $\theta$  is the identity function,  $(\hat{\mathcal{X}}^*, \hat{\mathcal{X}}, \mathcal{L}, \mathbb{Z}_p)$  is a diverse group. We remark, however, that one does not need to know diverse groups to understand our paper.

*Example 1 (SPHF for DDH).* Let us illustrate this framework for the DDH language: let  $g, h$  be two generators of a cyclic group  $\mathbb{G}$  of prime order  $p$ , let  $\mathcal{X} = \mathbb{G}^2$  and  $\mathcal{L} = \{(g^r, h^r)^\top \in \mathcal{X} \mid r \in \mathbb{Z}_p\}$ . We set  $\hat{\mathcal{X}} = \mathcal{X}$ ,  $\hat{\mathcal{L}} = \mathcal{L}$  and  $\theta$  the identify function so that  $C = \hat{C} = (u, v)^\top$ .  $\hat{\mathcal{L}}$  is generated by the column vector  $\mathbf{F}_1 = (g, h)^\top$ . The witness for  $C = (g^r, h^r)^\top$  is  $\lambda_1 = r$ . The hashing key

<sup>3</sup> In this work, we need a multilinear map for which DDH,  $\kappa$ -Lin, or any MDDH assumption [EHK<sup>+</sup>13] hold in the multilinear groups. Unfortunately, as explained in Footnote 2, no current candidate multilinear map construction is known to work for our framework.

<sup>4</sup> Graded rings were named after graded encodings systems [GGH13] and are unrelated to the mathematical notion of graded rings.

$\text{hk} = \alpha \stackrel{\$}{\leftarrow} \hat{\mathcal{X}}^*$  can be represented by a row vector  $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}_p^{1 \times 2}$  and

$$\begin{aligned} \text{hp} &= \gamma_1 = \alpha(\Gamma_1) = \alpha \bullet \Gamma_1 = g^{\alpha_1} \cdot h^{\alpha_2} \\ H &= \alpha(\hat{C}) = \alpha \bullet \hat{C} = u^{\alpha_1} \cdot v^{\alpha_2} = \gamma_1 \bullet r = \gamma_1^r. \end{aligned}$$

This is exactly the original SPHF of Cramer and Shoup for the DDH language in [CS02].

**Remark on the Notation of Vectors (Transposition) and Link with [EHK<sup>+</sup>13].** Compared to [BBC<sup>+</sup>13], in this paper, we transposed all the vectors and matrices: elements of  $\mathcal{X}$  are now column vectors, while hashing keys (elements of  $\mathcal{X}^*$ ) are row vectors. This seems more natural and makes our notation closer to the one of Escala et al. [EHK<sup>+</sup>13].

**Warm up: Conjunction of Languages.** As a warm up, let us first construct the conjunction  $\mathcal{L} = \mathcal{L}_1 \times \mathcal{L}_2$  of two languages  $\mathcal{L}_1 \subset \mathcal{X}_1$  and  $\mathcal{L}_2 \subset \mathcal{X}_2$  supported by the generic framework, in a more algebraic way than the one in [ACP09]. We can just set:

$$\begin{aligned} \hat{\mathcal{X}} &:= \hat{\mathcal{X}}_1 \times \hat{\mathcal{X}}_2 & n &:= n_1 + n_2 \\ \hat{\mathcal{L}} &:= \hat{\mathcal{L}}_1 \times \hat{\mathcal{L}}_2 & k &:= k_1 + k_2 \\ \theta((C_1, C_2)) = \hat{C} &:= \begin{pmatrix} \theta_1(C_1) \\ \theta_2(C_2) \end{pmatrix} & (\Gamma_i)_{i=1}^k &:= \left( \begin{pmatrix} \Gamma_i^{(1)} \\ \mathbf{0} \end{pmatrix}_{i=1}^{k_1}, \begin{pmatrix} \mathbf{0} \\ \Gamma_i^{(2)} \end{pmatrix}_{i=1}^{k_2} \right) \end{aligned}$$

This is what is implicitly done in all conjunctions of SPHFs in [BBC<sup>+</sup>13], for example.

*Example 2 (SPHF for Conjunction of DDH).* Let  $g_1, h_1, g_2, h_2$  be four generators of a cyclic group  $\mathbb{G}$  of prime order  $p$ . Let  $\mathcal{X}_1 = \mathcal{X}_2 = \mathbb{G}^2$  and  $\mathcal{L}_i = \{(g_i^{r_i}, h_i^{r_i})^\top \in \mathcal{X}_i \mid r_i \in \mathbb{Z}_p\}$  for  $i = 1, 2$ . We set  $\hat{\mathcal{X}}_i = \mathcal{X}_i$ ,  $\hat{\mathcal{L}}_i = \mathcal{L}_i$  and  $\theta_i$  the identify function so that  $C_i = \hat{C}_i = (u_i, v_i)^\top$ , for  $i = 1, 2$ .  $\hat{\mathcal{L}}_i$  is generated by the column vector  $\Gamma_1^{(i)} = (g_i, h_i)^\top$ . The witness for  $C_i = (g_i^{r_i}, h_i^{r_i})^\top$  is  $\lambda_1^{(i)} = r_i$ . Then, the SPHF for the conjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$  is defined by:

$$\begin{aligned} \hat{\mathcal{X}} &:= \hat{\mathcal{X}}_1 \times \hat{\mathcal{X}}_2 = \mathbb{G}^4 & n &= 4 & k &= 2 \\ \hat{\mathcal{L}} &:= \hat{\mathcal{L}}_1 \times \hat{\mathcal{L}}_2 = \{(g_1^{r_1}, h_1^{r_1}, g_2^{r_2}, h_2^{r_2})^\top \mid r_1, r_2 \in \mathbb{Z}_p\} \\ \Gamma_1 &:= (g_1, h_1, 1, 1)^\top \in \mathbb{G}^4 & \Gamma_2 &:= (1, 1, g_2, h_2)^\top \in \mathbb{G}^4 \\ \theta(C) &:= \hat{C} := (u_1, v_1, u_2, v_2)^\top \in \mathbb{G}^4 \text{ for } C = (C_1, C_2) = ((u_1, v_1)^\top, (u_2, v_2)^\top) \end{aligned}$$

The hashing key  $\text{hk} = \alpha \stackrel{\$}{\leftarrow} \hat{\mathcal{X}}^*$  can be represented by a row vector  $\alpha = (\alpha_1, \alpha_2, \alpha_3, \alpha_4) \in \mathbb{Z}_p^{1 \times 4}$  and

$$\begin{aligned} \text{hp} &= \begin{pmatrix} \gamma_1 \\ \gamma_2 \end{pmatrix} = \begin{pmatrix} \alpha \bullet \Gamma_1 \\ \alpha \bullet \Gamma_2 \end{pmatrix} = \begin{pmatrix} g_1^{\alpha_1} \cdot h_1^{\alpha_2} \\ g_2^{\alpha_3} \cdot h_2^{\alpha_4} \end{pmatrix} \\ H &= \alpha(\hat{C}) = \alpha \bullet \hat{C} = u_1^{\alpha_1} \cdot v_1^{\alpha_2} \cdot u_2^{\alpha_3} \cdot v_2^{\alpha_4} = \gamma_1 \bullet r_1 + \gamma_2 \bullet r_2 = \gamma_1^{r_1} \cdot \gamma_2^{r_2}. \end{aligned}$$

**Disjunction of Languages.** We first remark we cannot naively extend the previous construction by choosing  $\hat{\mathcal{X}} = \hat{\mathcal{X}}_1 \times \hat{\mathcal{X}}_2$  and  $\hat{\mathcal{L}} = (\hat{\mathcal{L}}_1 \times \hat{\mathcal{X}}_2) \cup (\hat{\mathcal{X}}_1 \times \hat{\mathcal{L}}_2)$ , because, in this case  $\hat{\mathcal{L}}$  is not a subspace, and the subspace generated by  $\hat{\mathcal{L}}$  is  $\hat{\mathcal{X}}_1 \times \hat{\mathcal{X}}_2$ . That is why we use tensor products of vector spaces instead of direct product of vector spaces. Concretely, we set

$$\begin{aligned} \hat{\mathcal{X}} &:= \hat{\mathcal{X}}_1 \otimes \hat{\mathcal{X}}_2 & n &:= n_1 n_2 \\ \hat{\mathcal{L}} &:= \langle (\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{X}}_2) \cup (\hat{\mathcal{X}}_1 \otimes \hat{\mathcal{L}}_2) \rangle & k &:= k_1 n_2 + n_1 k_2 \\ \theta(C) = \hat{C} &:= \hat{C}_1 \otimes \hat{C}_2 \end{aligned}$$

where the notation  $\langle V \rangle$  is the vector space generated by  $V$ . The vectors  $\mathbf{F}_i$  are described in detail in the core of the paper. This construction works since, if  $\hat{\mathbf{C}}_1 \otimes \hat{\mathbf{C}}_2 \in \hat{\mathcal{L}}$  then, thanks to properties of the tensor product,  $\hat{\mathbf{C}}_1 \in \hat{\mathcal{L}}_1$  or  $\hat{\mathbf{C}}_2 \in \hat{\mathcal{L}}_2$ .

It is important to remark that computing a tensor product implies computing a multiplication. So if  $\hat{\mathbf{C}}_1$  in  $\hat{\mathcal{X}}_1$  and  $\hat{\mathbf{C}}_2$  in  $\hat{\mathcal{X}}_2$  are over some cyclic groups  $\mathbb{G}_1$  and  $\mathbb{G}_2$ , we need a bilinear map  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  to actually be able to compute  $\hat{\mathbf{C}}_1 \otimes \hat{\mathbf{C}}_2$ . More generally, doing the disjunction of  $K$  languages over cyclic groups requires a  $K$ -way multilinear map. This can be seen in the following example and we formally deal with this technicality in the core of the paper.

*Example 3 (SPHF for Disjunction of DDH).* Let us use the same notation as in Example 2, except that this time  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$  is an asymmetric bilinear group ( $e$  is a bilinear map:  $\mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$ ),  $g_1, h_1$  are generators of  $\mathbb{G}_1$ ,  $g_2, h_2$  are generators of  $\mathbb{G}_2$ , and  $\mathcal{X}_i = \hat{\mathcal{X}}_i = \mathbb{G}_i^2$  (instead of  $\mathbb{G}^2$ ) for  $i = 1, 2$ .

The disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$  is defined by

$$\begin{aligned} \hat{\mathcal{X}} &:= \hat{\mathcal{X}}_1 \otimes \hat{\mathcal{X}}_2 = \mathbb{G}_T^4 & n &:= 4 \\ \hat{\mathcal{L}} &:= \langle (\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{X}}_2) \cup (\hat{\mathcal{X}}_1 \otimes \hat{\mathcal{L}}_2) \rangle & k &:= 4 \\ \mathbf{F}_1 &:= \begin{pmatrix} g_1 \\ h_1 \end{pmatrix} \otimes \begin{pmatrix} 1 \in \mathbb{Z}_p \\ 0 \in \mathbb{Z}_p \end{pmatrix} = \begin{pmatrix} g_1^1 \\ g_1^0 \\ h_1^1 \\ h_1^0 \end{pmatrix} = \begin{pmatrix} g_1 \\ 1 \\ h_1 \\ 1 \end{pmatrix} \in \mathbb{G}_1^4 \\ \mathbf{F}_2 &:= \begin{pmatrix} g_1 \\ h_1 \end{pmatrix} \otimes \begin{pmatrix} 0 \in \mathbb{Z}_p \\ 1 \in \mathbb{Z}_p \end{pmatrix} = \begin{pmatrix} g_1^0 \\ g_1^1 \\ h_1^0 \\ h_1^1 \end{pmatrix} = \begin{pmatrix} 1 \\ g_1 \\ 1 \\ h_1 \end{pmatrix} \in \mathbb{G}_1^4 \\ \mathbf{F}_3 &:= \begin{pmatrix} 1 \in \mathbb{Z}_p \\ 0 \in \mathbb{Z}_p \end{pmatrix} \otimes \begin{pmatrix} g_2 \\ h_2 \end{pmatrix} = \begin{pmatrix} g_2^1 \\ h_2^1 \\ g_2^0 \\ h_2^0 \end{pmatrix} = \begin{pmatrix} g_2 \\ h_2 \\ 1 \\ 1 \end{pmatrix} \in \mathbb{G}_2^4 \\ \mathbf{F}_4 &:= \begin{pmatrix} 0 \in \mathbb{Z}_p \\ 1 \in \mathbb{Z}_p \end{pmatrix} \otimes \begin{pmatrix} g_2 \\ h_2 \end{pmatrix} = \begin{pmatrix} g_2^0 \\ h_2^0 \\ g_2^1 \\ h_2^1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ g_2 \\ h_2 \end{pmatrix} \in \mathbb{G}_2^4 \\ \theta(C) = \hat{\mathbf{C}} &:= \hat{\mathbf{C}}_1 \otimes \hat{\mathbf{C}}_2 = (u_1 \bullet u_2, u_1 \bullet v_2, v_1 \bullet u_2, v_1 \bullet v_2)^\top \\ &= (e(u_1, u_2), e(u_1, v_2), e(v_1, u_2), e(v_1, v_2))^\top \in \mathbb{G}_T^4, \end{aligned}$$

for  $C = (C_1, C_2) = ((u_1, v_1), (u_2, v_2))$ . The generating family of  $\hat{\mathcal{L}}$  we used here is  $(\mathbf{F}_1, \mathbf{F}_2, \mathbf{F}_3, \mathbf{F}_4)$ . As seen after, if we know the witness  $r_1$  for  $C_1$ , we can use  $\mathbf{F}_1$  and  $\mathbf{F}_2$  to compute the hash value of  $C = (C_1, C_2)$ , while if we know the witness  $r_2$  for  $C_2$ , we can use  $\mathbf{F}_3$  and  $\mathbf{F}_4$  to compute the hash value of  $C$ . Obviously this generating family is not free, since  $\hat{\mathcal{L}}$  has dimension 3 and this family has cardinality 4.

The witnesses  $\lambda$  for a word  $C = (C_1, C_2)$  are

$$\begin{cases} (r_1 \bullet u_2, r_1 \bullet v_2, 0, 0) & \text{if } (u_1, v_1) = (g^{r_1}, h^{r_1}) \quad (\text{i.e., if } r_1 \text{ is a witness for } C_1) \\ (0, 0, r_2 \bullet u_1, r_2 \bullet v_1) & \text{if } (u_2, v_2) = (g^{r_2}, h^{r_2}) \quad (\text{i.e., if } r_2 \text{ is a witness for } C_2), \end{cases}$$

the hashing key  $\text{hk} = \alpha \stackrel{\$}{\leftarrow} \hat{\mathcal{X}}^*$  can be represented by a row vector  $\alpha = (\alpha_1, \alpha_2, \alpha_3, \alpha_4) \in \mathbb{Z}_p^{1 \times 4}$  and

$$\begin{aligned} \text{hp} &= (\gamma_1, \gamma_2, \gamma_3, \gamma_4)^\top = (g_1^{\alpha_1} \cdot h_1^{\alpha_3}, g_1^{\alpha_2} \cdot h_1^{\alpha_4}, g_2^{\alpha_1} \cdot h_2^{\alpha_2}, g_2^{\alpha_3} \cdot h_2^{\alpha_4})^\top \in \mathbb{G}_1^2 \times \mathbb{G}_2^2 \\ H &= \alpha(\hat{\mathcal{C}}) = \hat{\mathcal{C}} \bullet \alpha = e(u_1, u_2)^{\alpha_1} \cdot e(u_1, v_2)^{\alpha_2} \cdot e(v_1, u_2)^{\alpha_3} \cdot e(v_1, v_2)^{\alpha_4} \\ &= \begin{cases} r_1 \bullet u_2 \bullet \gamma_1 + r_1 \bullet v_2 \bullet \gamma_2 = e(\gamma_1, u_2)^{r_1} e(\gamma_2, v_2)^{r_1}, & \text{if } (u_1, v_1) = (g_1^{r_1}, h_1^{r_1}) \\ r_2 \bullet u_1 \bullet \gamma_3 + r_2 \bullet v_1 \bullet \gamma_4 = e(u_1, \gamma_3)^{r_2} e(v_1, \gamma_4)^{r_2}, & \text{if } (u_2, v_2) = (g_2^{r_2}, h_2^{r_2}) \end{cases} \end{aligned}$$

The last equalities, which show the way the projection hashing works, explain the choice of the generating family  $(\mathbf{F}_i)_i$ .

## 2.2 Main Application: One-Time Simulation-Sound NIZK Arguments

The language of the NIZK is  $\mathcal{L}_1$ , while  $\mathcal{L}_2$  is a hard subset membership language used to build the NIZK. For the sake of simplicity, we suppose that  $\mathcal{L}_2 = \hat{\mathcal{L}}_2$ ,  $\mathcal{X}_2 = \hat{\mathcal{X}}_2$ , and  $\theta_2$  is the identity function. We will consider the SPHF of the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$ , so we need to suppose that it is possible to build it. For this high level overview, let us just suppose that  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$  is a bilinear group and that  $\mathcal{L}_1$  is defined over  $\mathbb{G}_1$ ,  $\mathcal{L}_2$  over  $\mathbb{G}_2$ . If DDH holds in  $\mathbb{G}_2$ ,  $\mathcal{L}_2$  can just be the DDH language in  $\mathbb{G}_2$  recalled in Example 1.

The common reference string is a projection key  $\text{hp}$  for the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$ , while the trapdoor (to simulate proofs) is the hashing key. Essentially, a proof  $\pi = (\pi_{i_2})_{i_2}$  for a statement  $C_1$  is just a vector of the hash values of  $(C_1, \mathbf{e}_{2, i_2})$  where  $(\mathbf{e}_{2, i_2})_{i_2}$  are the scalar vectors of the canonical base of  $\hat{\mathcal{X}}_2$ . These hash values are  $\pi_{i_2} = \alpha(\hat{\mathcal{C}}_1 \otimes \mathbf{e}_{2, i_2})$ , and can also be computed from the projection key  $\text{hp}$  and a witness for  $\hat{\mathcal{C}}_1$ .

The basic idea is that a valid proof for a word  $C_1 \in \mathcal{L}_1$  enables us to compute the hash value  $H'$  of  $(C_1, C_2)$  for any word  $C_2 \in \hat{\mathcal{X}}_2$ , by linearly combining elements of the proof, since any word  $C_2$  can be written as a linear combination of  $(\mathbf{e}_{2, i_2})_{i_2}$ :

$$H' := \sum_{i_2} \pi_{i_2} \bullet C_{2, i_2} = \sum_{i_2} \alpha(\hat{\mathcal{C}}_1 \otimes (C_{2, i_2} \bullet \mathbf{e}_{2, i_2})) = \alpha(\hat{\mathcal{C}}_1 \otimes C_2),$$

if  $C_2 = \sum_{i_2} C_{2, i_2} \bullet \mathbf{e}_{1, i_2}$ . Hence, for any word  $C_2 \in \mathcal{L}_2$  for which we know a witness, we can compute the hash value of  $(C_1, C_2)$ , either using a valid proof for  $C_1$  (as  $H'$  above), or directly using the witness of  $C_2$  and the projection key  $\text{hp}$  (as for any SPHF for a disjunction).

To check a proof, we basically check that for any word  $C_2 \in \mathcal{L}_2$ , these two ways of computing the hash value of  $(C_1, C_2)$  yields the same result. Thanks to the linearity of the language  $\mathcal{L}_2$ , it is sufficient to make this test for a family of words  $C_2$  which generate  $\mathcal{L}_2$ , such as the words  $\mathbf{F}_j^{(2)}$  (for  $j = 1, \dots, k_2$ ). We recall that the witness for  $\mathbf{F}_j^{(2)}$  is the column vector  $(0, \dots, 0, 1, 0, \dots, 0)^\top \in \mathbb{Z}_p^{k_2}$ , where the  $j$ -th coordinate is 1.

The trapdoor, i.e., the hashing key, clearly enables us to simulate any proof, and the resulting proofs are perfectly indistinguishable from normal ones, hence the perfect zero-knowledge property. Moreover, the soundness comes from the fact that a proof for a word  $C_1 \notin \mathcal{L}_1$  can be used to break the hard subset membership in  $\mathcal{L}_2$ .

More precisely, let us consider a soundness adversary which takes as input the projection key  $\text{hp}$  and which outputs a word  $C_1 \notin \mathcal{L}_1$  and a valid proof  $\pi$  for  $C_1$ . On the one hand, such a valid proof enables us to compute the hash value  $H'$  of  $(C_1, C_2)$  for any word  $C_2 \in \mathcal{L}_2$ , by linearly combining elements of the proofs (as seen above), and the validity of the proof ensures the resulting value  $H'$  is correct if  $C_2 \in \mathcal{L}_2$ . On the other hand, we can also compute a hash value  $H$  of  $(C_1, C_2)$  for any  $C_2 \in \mathcal{X}_2$  using the hashing key  $\text{hk}$ . Then, if  $C_2 \in \mathcal{L}_2$ , necessarily  $H = H'$ , while if  $C_2 \notin \mathcal{L}_2$ , the smoothness ensures that  $H$  looks completely random when given only  $\text{hp}$ . Since  $H'$  does not depend on  $\text{hk}$  but only on  $\text{hp}$ , it is different from  $H$  with overwhelming probability. Therefore, we can use such an adversary to solve the hard subset membership problem in  $\mathcal{L}_2$  (namely, the DDH in  $\mathbb{G}_2$  in the example below).

*Example 4 (NIZK for DDH in  $\mathbb{G}_1$ , assuming DDH in  $\mathbb{G}_2$ ).* Using the SPHF in Example 3, the proof for a word  $C_1 = (u_1 = g_1^r, v_1 = h_1^r) \in \mathbb{G}_1^2$  is the vector  $\boldsymbol{\pi} = (\pi_1, \pi_2) \in \mathbb{G}_1^2$  where:  $\pi_1$  is the hash value of  $(C_1, (1, 0)^\top) \in \mathbb{G}_1^2 \times \mathbb{Z}_p^2$  and  $\pi_2$  is the hash value of  $(C_1, (0, 1)^\top) \in \mathbb{G}_1^2 \times \mathbb{Z}_p^2$ . Concretely we have:

$$\pi_1 = \gamma_1 \bullet r = \gamma_1^r \in \mathbb{G}_1 \qquad \pi_2 = \gamma_2 \bullet r = \gamma_2^r \in \mathbb{G}_1.$$

This proof is valid if and only if:

$$e(\pi_1, g_2) \cdot e(\pi_2, h_2) = \pi_1 \bullet g_2 + \pi_2 \bullet h_2 \stackrel{?}{=} u_1 \bullet \gamma_3 + v_1 \bullet \gamma_4 = e(u_1, \gamma_3) \cdot e(v_1, \gamma_4).$$

This check can be done using the common reference string  $\mathbf{hp} = (\gamma_1, \gamma_2, \gamma_3, \gamma_4)$ .

Finally, to simulate a proof for  $C_1 = (u_1, v_1)$  without knowing any witness for  $C_1$  but knowing the trapdoor  $\mathbf{hk} = \boldsymbol{\alpha} = (\alpha_1, \alpha_2, \alpha_3, \alpha_4) \in \mathbb{Z}_p^{1 \times 4}$ , we compute  $\pi_1$  and  $\pi_2$  as follows:

$$\pi_1 := u_1 \bullet \alpha_1 + v_1 \bullet \alpha_3 = u_1^{\alpha_1} \cdot v_1^{\alpha_3} \qquad \pi_2 := u_1 \bullet \alpha_2 + v_1 \bullet \alpha_4 = u_1^{\alpha_2} \cdot v_1^{\alpha_4}.$$

To get a one-time simulation-sound NIZK, we replace the SPHF over  $\mathcal{L}_1$  by a stronger kind of SPHF for which, roughly speaking, the hash value of a word  $C \notin \mathcal{L}_1$  appears random even if we are given the projection key  $\mathbf{hp}$  and the hash value of another word  $C \in \mathcal{X}_1$  of our choice. We show that it is always possible to transform a normal SPHF into this stronger variant, assuming the existence of collision-resistant hash functions<sup>5</sup>.

### 2.3 Other Applications

**TSPHF.** A TSPHF is an extension of an SPHF, with an additional CRS and an associated trapdoor, where the latter provides a way to efficiently compute the hash value of any word  $C$  knowing only the projection key  $\mathbf{hp}$ . Since  $\mathbf{hp}$  now needs to contain enough information to compute the hash value of any word in  $\mathcal{X}$ , the smoothness property of TSPHFs is no longer statistical but computational. As shown in [BBC<sup>+</sup>13], TSPHFs can be used to construct two-round zero-knowledge protocols and the most efficient one-round PAKE in the standard model.

TSPHF is a direct application of disjunctions of SPHFs: as for NIZK, the language we are interested in is  $\mathcal{L}_1$ , while  $\mathcal{L}_2$  is a hard subset membership language. The common reference string contains a word  $C_2 \in \mathcal{L}_2$ , and the trapdoor is just a witness  $w_2$  for this word. The hash value of some  $C_1 \in \mathcal{X}_1$ , is the hash value of  $(C_1, C_2)$  for the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$ , which can be computed in two or three ways: using  $\mathbf{hk}$ , or using  $\mathbf{hp}$  and  $w_1$  (classical projection hashing — possible only when  $C_1 \in \mathcal{L}_1$  and  $w_1$  is a witness for it), or using  $\mathbf{hp}$  and  $w_2$  (trapdoor). The smoothness comes from the hard subset membership property of  $\mathcal{L}_2$  (which says that this common reference string is indistinguishable from a word  $C_2 \notin \mathcal{L}_2$ ) and the fact that when  $C_2 \notin \mathcal{L}_2$ , the hash value of  $(C_1, C_2)$  appears random by smoothness when  $C_1 \notin \mathcal{L}_1$ , given only  $\mathbf{hp}$ .

The resulting TSPHF is slightly less efficient than the construction in [BBC<sup>+</sup>13]: if  $\mathcal{L}_2$  corresponds to the DDH language (Example 1), the projection key contains less than twice more elements than the original construction. But it has the advantage of handling more languages, since contrary to the original construction, there is no need to have a trapdoor  $\mathcal{T}_{\text{crs}}$  for  $\text{crs}$  which enables us to compute the discrete logarithms of all entries of  $\Gamma_1$  (a property called witness-samplability in [JR13])<sup>6</sup>.

<sup>5</sup> Actually, the use of collision-resistant hash functions could be avoided, but that would make the construction much less efficient.

<sup>6</sup> However, due to the definition of computational smoothness of TSPHF in [BBC<sup>+</sup>13], it is still required to have such a trapdoor  $\mathcal{T}_{\text{crs}}$  enabling to check whether a word  $C_1$  is in  $\mathcal{L}_1$  or not. It may be possible to change definitions to avoid that, but in all applications we are aware of, this is never a problem.

**One-Time Linearly Homomorphic Structure-Preserving Signature.** We can obtain the one-time linearly homomorphic structure-preserving signature scheme of messages in  $\mathbb{G}_1^{n_1}$  of Libert et al. [LPJY13] and extend it to work under any hard-subset membership language assumption, such as the DDH language in Example 1 but also DLin or any MDDH assumption [EHK<sup>+</sup>13] as seen later (instead of just DLin as in the original paper). The construction is very similar to our NIZK construction.

Let  $\mathcal{L}_2 = \hat{\mathcal{L}}_2 \subset \mathcal{X}_2 = \hat{\mathcal{X}}_2$  be a hard membership language and  $\mathcal{X}_1 = \hat{\mathcal{X}}_1 = \mathbb{G}_1^{n_1}$  (the language  $\mathcal{L}_1 = \hat{\mathcal{L}}_1$  will be defined later). The secret key is the hashing key  $\text{hk} = \alpha$  of the SPHF of the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$  (notice that it does not depend on the language  $\hat{\mathcal{L}}_1$  but only on  $\hat{\mathcal{X}}_1$ ), while the public key is the associated projection key when  $\mathcal{L}_1 = \hat{\mathcal{L}}_1 = \{0\}$ . The signature of a message  $\mathbf{M} \in \hat{\mathcal{X}}_1 = \mathbb{G}_1^{n_1}$  is the vector of the hash values of  $(\mathbf{M}, \mathbf{e}_{2,i_2})$  where  $(\mathbf{e}_{2,i_2})_{i_2}$  are the scalar vectors of the canonical base of  $\hat{\mathcal{X}}_2$ . It can be computed using the secret key  $\text{hk}$ . Actually, this corresponds to the NIZK proof of  $\mathbf{M}$  (computed using the trapdoor  $\text{hk}$ ), in our NIZK scheme above. Checking the signature can be done by checking the validity of the proof using the projection key  $\text{hp}$  when  $\hat{\mathcal{L}}_1 = \{0\}$ .

Finally, to prove the one-time unforgeability, we just need to remark that knowing signatures of  $\mathbf{M}_1, \dots, \mathbf{M}_n \in \hat{\mathcal{X}}_1$  actually can be seen as knowing a projection key  $\text{hp}'$  associated to  $\text{hk}$  when  $\hat{\mathcal{L}}_1$  is the subspace generated by  $\Gamma_1 := \mathbf{M}_1, \dots, \Gamma_n := \mathbf{M}_n$ . Therefore, generating a signature of a message  $\mathbf{M}$  linearly independent of these messages means generating an NIZK proof for a statement  $\mathbf{M} \notin \hat{\mathcal{L}}_1$ , which has been shown to be hard thanks to the smoothness property of the SPHF and the hard subset membership property of  $\mathcal{L}_2$ .

**One-Round GPAKE.** A one-round group password-based authenticated key exchange (GPAKE) is a protocol enabling  $n$  users sharing a password  $\text{pw}$  to establish a common secret key  $\text{sk}$  in only one round: just by sending one flow. For such protocols, online dictionary attacks, which consist in guessing the password of an honest user and running honestly the protocol with this guessed password, are unavoidable. As a result, the best security that one can hope for is to limit the adversary to at most one password guess per interaction with an honest party. In order to capture this intuition, the formal security model of Abdalla et al. [ABCP06], which is recalled in Appendix D.2, essentially guarantees that, in a secure GPAKE scheme, no adversary having at most  $q$  interactions with honest parties can win with probability higher than  $q/N$ , where  $N$  is the number of possible passwords. Here, winning means distinguishing a real key (generated by an honest user following the protocol, controlled by the challenger) from a random key  $\text{sk}$ .

Our construction is a non-trivial extension of the one-round PAKE of Benhamouda et al. in [BBC<sup>+</sup>13], which is an efficient instantiation of the Katz-Vaikuntanathan framework [KV11]. Basically, a user  $U_i$  ( $1 \leq i \leq n$ ) sends an extractable commitment  $C_i$  (i.e., an encryption for some public key  $\text{ek}$  in the common reference string) of his password  $\text{pw}$  together with a projection key  $\text{hp}_i$  for the disjunction of  $n - 1$  languages of valid commitments of  $\text{pw}$  (words in this disjunction are tuple  $\mathbf{C}_i = (C_j)_{j \neq i}$  of  $n - 1$  commitments where at least one of them is a valid commitment of  $\text{pw}$ ). Each partner  $U_j$  of this user  $U_i$  can compute the hash value  $H_i$  of the tuple  $\mathbf{C}_i$ , with  $\text{hp}_i$ , just by additionally knowing the witness (the random coins) of his commitment  $C_j$  onto  $\text{pw}$ , while  $U_i$  uses  $\text{hk}_i$ . The resulting secret key  $K$  is just the XOR of all these hash values (one per hashing key, i.e., one per user):  $\text{sk} = H_1 \text{ xor } \dots \text{ xor } H_n$ .

At a first glance, one may wonder why our construction relies on a disjunction and not on a conjunction: intuitively, as a user, we would like that every other user commits to the same password as ours. Unfortunately, in this case, nobody would be able to compute the hash value of the expected conjunction, except for the user who generated the hashing key. This is because this computation would require the knowledge of all the witnesses and there is no way for a user to know the witness for a commitment of another user. However, by relying on a disjunction, each user is only required to know the witness for his own commitment.

To understand why this is a secure solution, please note that the challenger (in the security game) can make dummy commitments for the honest players he controls. Then, if no corrupted

user (controlled by the adversary) commits to a correct password, the tuple of the  $n - 1$  other commitments would not be a valid word in the disjunction language (no commitment would be valid) for any of the honest users. Hence, the hash value would appear random to the adversary. The complete proof is a very delicate extension of the proof of the one-round PAKE of Katz and Vaikuntanathan in [KV11], and may be of independent interest.

Due to recent results by Cheon et al. [CHL<sup>+</sup>14], currently no concrete instantiation of our GPAKE is known for  $n \geq 4$  (see Footnote 2 on page 3). For  $n = 3$ , our scheme only relies on bilinear groups and is practical

## 2.4 Pseudo-Random Projective Hash Functions and More Efficient Applications

**Pseudo-Random Projective Hash Functions.** As already explained in Section 1.1, for our (one-time simulation-sound) NIZK and our TSPHF, the second language  $\mathcal{L}_2$  is used to provide extra features. Security properties come from its hard subset membership property. However, hard subset membership comes at a cost: the dimension  $k_2$  of  $\hat{\mathcal{L}}_2$  has to be at least 1 to be non-trivial, and so the dimension  $n_2$  of  $\hat{\mathcal{X}}_2$  is at least 2, otherwise  $\hat{\mathcal{L}}_2 = \hat{\mathcal{X}}_2$ . This makes the projection key of the disjunction of  $\mathcal{L}_1$  and  $\mathcal{L}_2$  of size  $k_1 n_2 + n_1 k_2 \geq 2k_1 + n_1$ .

Intuitively, what we would like is to be able to have a language  $\mathcal{L}_2$  where  $n_2 = k_2 = 1$ . Such a language would clearly not be hard subset membership, and the smoothness property of SPHF would be completely trivial, since  $\hat{\mathcal{X}}_2 \setminus \hat{\mathcal{L}}_2$  would be empty. That is why we introduce the notion of pseudo-randomness which says that the hash value of a word  $C_2$  chosen at random in  $\mathcal{X}_2$  (and for implicit languages parameters  $\text{crs}_2$  chosen at random), the hash value of  $C_2$  looks random, given only the projection key.

Under DDH in  $\mathbb{G}_2$ , we can simply choose  $\text{crs}_2 = g_2$  a random generator in  $\mathbb{G}_2$ ,  $\mathcal{X}_2 = \hat{\mathcal{X}}_2 = \mathcal{L}_2 = \hat{\mathcal{L}}_2 = \mathbb{G}_2$ , and  $\theta_2$  the identity function. The witness for a word  $C_2 \in \mathbb{G}_2$  is just its discrete logarithm in base  $g_2$ , and so  $\hat{\mathcal{L}}_2$  is seen as generated by the vector  $\mathbf{r}_1^{(2)} = (g_2)$ . An hashing key  $\text{hk}$  is just a random scalar  $\alpha \in \mathbb{Z}_p$ , the associated projection key is  $\text{hp} = g_2^\alpha$ . Finally the hash value is  $H = C_2^\alpha$ . It can also be computed using  $\text{hp}$  if we know the discrete logarithm of  $C_2$ . The DDH assumption says that if  $g_2, \text{hp} = g_2^\alpha, C_2$  are chosen uniformly at random in  $\mathbb{G}_2$ , it is hard to distinguish  $H = C_2^\alpha$  from a random group element  $H \in \mathbb{G}_2$ ; hence the pseudo-randomness.

**Mixed Pseudo-Randomness.** In all our applications, we are not really interested in the SPHF on  $\mathcal{L}_2$  but in the SPHF on the disjunction  $\mathcal{L}$  of  $\mathcal{L}_1$  and  $\mathcal{L}_2$ . Of course, this SPHF would be smooth, but that property is again trivial, since all words  $(C_1, C_2)$  are in  $\mathcal{L}$ . We therefore again need a stronger property called *mixed pseudo-randomness* which roughly says that if  $\text{hk}$  is a random hashing key, if  $C_1 \notin \mathcal{L}_1$  and if  $C_2$  is chosen at random, the hash value of  $(C_1, C_2) \in \mathcal{L}$  appears random to any polynomial-time adversary, even given access to the projection key  $\text{hp}$ .

The proof of this property is quite technical and requires that it is possible to generate parameters of  $\mathcal{L}_1$  so that we know the discrete logarithm of the generators  $(\mathbf{r}_{i_1}^{(1)})_{i_1}$  of  $\hat{\mathcal{L}}_1$ . This last property is verified by most languages in which we are interested.

**Applications.** Using the mixed pseudo-randomness property, we easily get more efficient NIZK and TSPHF, just by replacing  $\mathcal{L}_2$  by a language  $\mathcal{L}_2$  with a pseudo-random Projective Hash Function. Getting a more efficient one-time simulation-sound NIZK is slightly more complex and is only detailed in the core of the paper. The resulting TSPHF construction actually corresponds to the original construction in [BBC<sup>+</sup>13]. But seeing it as a disjunction of an SPHF for the language we are interested in and of a pseudo-random projective hash function sheds new light on the construction and make it easier to understand, in our opinion.

### 3 Preliminaries

#### 3.1 Notation

As usual, all the players and the algorithms will be possibly probabilistic and stateful. Namely, adversaries can keep a state  $\text{st}$  during the different phases, and we denote by  $\overset{\$}{\leftarrow}$  the outcome of a probabilistic algorithm or the sampling from a uniform distribution. The statement  $y \overset{\$}{\leftarrow} \mathcal{A}(x; r)$  denotes the operation of running  $\mathcal{A}$  with input  $x$  and random tape  $r$  and storing the result in  $y$ . For the sake of clarity, we will sometimes omit the random tape  $r$  in  $\mathcal{A}(x; r)$ .

The qualities of adversaries will be measured by their successes and advantages in certain experiments  $\text{Exp}^{\text{sec}}$  or  $\text{Exp}^{\text{sec}-b}$  (between the cases  $b = 0$  and  $b = 1$ ), denoted  $\text{Succ}^{\text{sec}}(\mathcal{A}, \mathfrak{K})$  and  $\text{Adv}^{\text{sec}}(\mathcal{A}, \mathfrak{K})$  respectively, where  $\mathfrak{K}$  is the security parameter. Formal definition of all of this and of statistical distance can be found in Appendix A.1.

#### 3.2 Definition of SPHF

Let  $(\mathcal{L}_{\text{crs}})_{\text{crs}}$  be a family of NP languages indexed by  $\text{crs}$  with witness relation  $\mathcal{R}_{\text{crs}}$ , namely  $\mathcal{L}_{\text{crs}} = \{x \in \mathcal{X}_{\text{crs}} \mid \exists w, \mathcal{R}_{\text{crs}}(x, w) = 1\}$ , where  $(\mathcal{X}_{\text{crs}})_{\text{crs}}$  is a family set. The value  $\text{crs}$  is generated by a polynomial-time algorithm  $\text{Setup}_{\text{crs}}$  taking as input the unary representation of the security parameter  $\mathfrak{K}$ , and is usually a common reference string. The description of the underlying group or graded ring is implicit and not part of  $\text{crs}$ . We suppose that membership in  $\mathcal{X}_{\text{crs}}$  and  $\mathcal{R}_{\text{crs}}$  can be checked in polynomial time (in  $\mathfrak{K}$ ).

Finally, we suppose that  $\text{Setup}_{\text{crs}}$  also outputs a trapdoor  $\mathcal{T}_{\text{crs}}$  associated to  $\text{crs}$ . This trapdoor is empty  $\perp$  in most cases, but for some applications (namely NIZK constructions from Section 7), we require that  $\mathcal{T}_{\text{crs}}$  contains enough information to decide whether a word  $C \in \mathcal{X}$  is in  $\mathcal{L}$  or not (or slightly more information). We notice that for most, if not all, languages (we are interested in), it is easy to make  $\text{Setup}_{\text{crs}}$  output such a trapdoor, without changing the distribution of  $\text{crs}$ . In the sequel,  $\text{crs}$  is often dropped to simplify notation.

An SPHF over  $(\mathcal{L}_{\text{crs}})$  is defined by four polynomial-time algorithms:

- $\text{HashKG}(\text{crs})$  generates a hashing key  $\text{hk}$ ;
- $\text{ProjKG}(\text{hk}, \text{crs})$  derives a projection key  $\text{hp}$  from  $\text{hk}$ ;
- $\text{Hash}(\text{hk}, \text{crs}, C)$  outputs the hash value from the hashing key, for any  $\text{crs}$  and for any word  $C \in \mathcal{X}$ ;
- $\text{ProjHash}(\text{hp}, \text{crs}, C, w)$  outputs the hash value from the projection key  $\text{hp}$ , and the witness  $w$ , for a word  $C \in \mathcal{L}_{\text{crs}}$  (i.e.,  $\mathcal{R}_{\text{crs}}(C, w) = 1$ ).

The set of hash values is called the *range* and is denoted  $\Pi$ . It is often a cyclic group. We always suppose that its size is super-polynomial in the security parameter  $\mathfrak{K}$  so that the probability to guess correctly a uniform hash value is negligible.

An SPHF has to satisfy two properties:

- *Perfect correctness.* For any  $\text{crs}$  and any word  $C \in \mathcal{L}_{\text{crs}}$  with witness  $w$  (i.e., such that  $\mathcal{R}_{\text{crs}}(C, w) = 1$ ), for any  $\text{hk} \overset{\$}{\leftarrow} \text{HashKG}(\text{crs})$  and for  $\text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs})$ ,  $\text{Hash}(\text{hk}, \text{crs}, C) = \text{ProjHash}(\text{hp}, \text{crs}, C, w)$ ;
- *Perfect smoothness.* The hash value of a word outside the language looks completely random. More precisely, an SPHF is 0-smooth or perfectly smooth if for any  $\text{crs}$  and any  $C \notin \mathcal{L}_{\text{crs}}$ , the following two distributions are identical:

$$\left\{ (\text{hp}, H) \mid \text{hk} \overset{\$}{\leftarrow} \text{HashKG}(\text{crs}); \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); H \leftarrow \text{Hash}(\text{hk}, \text{crs}, C) \right\}$$

$$\left\{ (\text{hp}, H) \mid \text{hk} \overset{\$}{\leftarrow} \text{HashKG}(\text{crs}); \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); H \overset{\$}{\leftarrow} \Pi \right\}.$$

As shown in Appendix A.4, this definition of SPHF actually corresponds to a strong version of KV-SPHF [BBC<sup>+</sup>13] with perfect smoothness<sup>7</sup>. In particular, it is stronger than the definition of SPHF given in [CS02], where the smoothness is not perfect and is actually defined only for random elements  $C \in \mathcal{X} \setminus \mathcal{L}_{\text{crs}}$ . This is also slightly stronger than the 1-universal hash proof systems also defined in [CS02], since the hash value is supposed to look completely random and not just having some minimal entropy.

We restrict ourselves to this very strong form of SPHFs for the sake of simplicity and because most applications we consider require KV-SPHF. However, the construction of disjunctions of SPHFs can still easily be extended to weaker forms of SPHFs.

### 3.3 Hard Subset Membership Languages

A family of languages  $(\mathcal{L}_{\text{crs}} \subseteq \mathcal{X}_{\text{crs}})_{\text{crs}}$  is said to be a hard subset membership family of languages, if it is hard to distinguish between a word randomly drawn from inside  $\mathcal{L}_{\text{crs}}$  from a word randomly drawn from outside  $\mathcal{L}_{\text{crs}}$  (i.e., from  $\mathcal{X}_{\text{crs}} \setminus \mathcal{L}_{\text{crs}}$ ). This definition implicitly assumes the existence of a distribution over  $\mathcal{X}_{\text{crs}}$  and a way to sample efficiently words from  $\mathcal{L}_{\text{crs}}$  and from  $\mathcal{X}_{\text{crs}} \setminus \mathcal{L}_{\text{crs}}$ . More formally, this property is defined by the experiments  $\text{Exp}^{\text{subset-memb-}b}$  depicted in Fig. 6 on page 29, and holds when the advantage of a polynomial-time adversary against these experiments is negligible.

### 3.4 Bilinear Groups, Graded Rings and Assumptions

All our concrete constructions are based on bilinear groups, which are extensions of cyclic groups. Even though groups should be generated by an appropriate setup algorithm taking the security parameter as input, our definitions below use fixed groups for simplicity.

**Cyclic Groups and Bilinear Groups.**  $(p, \mathbb{G}, g)$  denotes a (multiplicative) cyclic group  $\mathbb{G}$  of order  $p$  and of generator  $g$ . When  $(p, \mathbb{G}_1, g_1)$ ,  $(p, \mathbb{G}_2, g_2)$ , and  $(p, \mathbb{G}_T, g_T)$  are three cyclic groups,  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$  or  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$  is called a *bilinear group* if  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  is a bilinear map (called a pairing) efficiently computable and such that  $e(g_1, g_2) = g_T$  is a generator of  $\mathbb{G}_T$ . It is called a *symmetric bilinear group* if  $\mathbb{G}_1 = \mathbb{G}_2 = \mathbb{G}$ . In this case, we denote it  $(p, \mathbb{G}, \mathbb{G}_T, e)$  and we suppose  $g = g_1 = g_2$ . Otherwise, if  $\mathbb{G}_1 \neq \mathbb{G}_2$ , it is called an *asymmetric bilinear group*.

**Graded Rings.** To understand the constructions in the article, it is sufficient to see a graded ring as a way to use ring operations  $(+, \bullet)$  over cyclic groups, bilinear groups, or even multilinear groups, as explained at the beginning of Section 2.1. In the sequel, we will often consider two multiplicatively compatible sub-graded rings  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  of some graded ring  $\mathfrak{G}$ : this basically means that it is possible to compute the product  $\bullet$  of any element of  $\mathfrak{G}_1$  with any element of  $\mathfrak{G}_2$ , and the result is in  $\mathfrak{G}$ . Concretely, as a first approach, it is possible to consider that  $\mathfrak{G}$  is a bilinear group  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$ , and that  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  corresponds to  $\mathbb{G}_1$  and  $\mathbb{G}_2$ : if  $u_1 \in \mathbb{G}_1$  and  $u_2 \in \mathbb{G}_2$ ,  $u_1 \bullet u_2 = e(u_1, u_2)$ . General and formal definitions are given in Appendix B.1.

**Assumptions.** The assumption we use the most is the SXDH assumption. The SXDH assumption over a bilinear group  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$  says the DDH assumption holds both in  $(p, \mathbb{G}_1, g_1)$  and  $(p, \mathbb{G}_2, g_2)$ , where the DDH assumption is defined as follows:

**Definition 5 (Decisional Diffie-Hellman (DDH)).** *The Decisional Diffie-Hellman assumption says that, in a cyclic group  $(p, \mathbb{G}, g)$ , when we are given  $(g^a, g^b, g^c)$  for unknown random  $a, b \xleftarrow{\$} \mathbb{Z}_p$ , it is hard to decide whether  $c = ab \bmod p$  (a DH tuple) or  $c \xleftarrow{\$} \mathbb{Z}_p$  (a random tuple).*

<sup>7</sup> The reader familiar with [BBC<sup>+</sup>13] may remark that in our definition, there is no parameter  $\text{aux}$  in addition to  $\text{crs}$ . This parameter is indeed useless in the context of KV-SPHFs (contrary to GL-SPHFs), as it can be included in the word  $C$ .

We also propose constructions under weaker assumptions than SXDH or DDH, namely  $\kappa$ -Lin, defined as follows:

**Definition 6 ( $\kappa$ -Lin).** *The  $\kappa$ -Linear assumption says that, in a cyclic group  $(p, \mathbb{G}, g)$ , when we are given  $(g^{a_1}, \dots, g^{a_\kappa}, g^{a_1 b_1}, \dots, g^{a_\kappa b_\kappa}, g^c)$  for unknown  $a_1, \dots, a_\kappa, b_1, \dots, b_\kappa \stackrel{\$}{\leftarrow} \mathbb{Z}_p$ , it is hard to decide whether  $c = b_1 + \dots + b_\kappa$  (a  $\kappa$ -Lin tuple) or  $c \stackrel{\$}{\leftarrow} \mathbb{Z}_p$  (a random tuple).*

The 1-Lin assumption is exactly DDH. One advantage of  $\kappa$ -Lin with  $\kappa \geq 2$  is that it can hold even in symmetric bilinear groups (where  $\mathbb{G}_1 = \mathbb{G}_2$ ) while DDH or SXDH do not. 2-Lin is also denoted DLin, and  $\kappa$ -Lin often means  $\kappa$ -Lin in  $\mathbb{G}_1$  and in  $\mathbb{G}_2$ . Actually, our constructions can easily be tweaked to support any MDDH assumption [EHK<sup>+</sup>13]. MDDH assumptions generalize  $\kappa$ -Lin assumptions.

## 4 Smooth Projective Hash Functions for Disjunctions

### 4.1 Generic Framework and Diverse Vector Spaces

Let us now recall the generic framework for SPHF. We have already seen the main ideas of this framework in Section 2.1. These ideas were stated in term of generic vector space. Even though using generic vector spaces facilitates the explanation of high level ideas, it is better to use an explicit basis when it comes to details. As already explained in Section 2.1 on page 6, compared to [BBC<sup>+</sup>13], all vectors and matrices are transposed.

Let  $\mathfrak{G}$  be a graded ring. We now set  $\hat{\mathcal{X}} = \mathfrak{G}^n$ , so that any vector  $\hat{C} \in \hat{\mathcal{X}}$  is a  $n$ -dimensional column vector. We denote by  $(\mathbf{e}_i)_{i=1}^n$  the canonical basis of  $\hat{\mathcal{X}}$ . The dual space of  $\hat{\mathcal{X}}$  is isomorphic<sup>8</sup> to  $\mathbb{Z}_p^{1 \times n}$ , and the hashing key  $\alpha \in \hat{\mathcal{X}}^*$  corresponds to the row vector  $\boldsymbol{\alpha} = (\alpha_i)_{i=1}^n$ , with  $\alpha_i = \alpha(\mathbf{e}_i)$ . We denote by  $\Gamma$  the matrix with columns  $(\Gamma_i)_{i=1}^k$ , where the family  $(\Gamma_i)$  generates the subspace  $\hat{\mathcal{L}}$  of  $\hat{\mathcal{X}}$ . Finally, we assume that for each coordinate of the vector  $\theta(C) \in \mathfrak{G}^n$ , the group in which this coordinate lies (called the index of the coordinate, in the formal description of graded rings in Appendix B.1) is independent of  $C$ .

We suppose that, a word  $C \in \mathcal{X}$  is in  $\mathcal{L}$  if and only if there exists  $\boldsymbol{\lambda} \in \mathfrak{G}^k$  such that:

$$\hat{C} := \theta(C) = \Gamma \bullet \boldsymbol{\lambda}.$$

We also assume the latter equality holds if and only if it would hold by only looking at the discrete logarithms (and not at the groups or indexes of entries or coordinates)<sup>9</sup>. In addition, we suppose that  $\boldsymbol{\lambda}$  can be computed easily from any witness  $w$  for  $C$ ; and in the sequel we often simply consider that  $w = \boldsymbol{\lambda}$ . By analogy with diverse groups [CS02], as explained in Section 2.1, we say that a tuple  $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, n, k, \Gamma, \theta)$  satisfying the above properties is a *diverse vector space*.

A summary of diverse vector spaces and the construction of SPHF over them can be found in Fig. 1. It is straightforward to see (and this is proven in [BBC<sup>+</sup>13]) that any SPHF defined by a discrete vector space  $\mathcal{V}$  as in Fig. 1 is correct and smooth.

### 4.2 Disjunctions of SPHF

As explained in Section 2.1, an SPHF for the disjunction of two languages  $\mathcal{L}_1$  and  $\mathcal{L}_2$  roughly consists in doing the tensor product of their related vector spaces  $\hat{\mathcal{X}}_1$  and  $\hat{\mathcal{X}}_2$ . However, our vector spaces are not classical vector spaces, since they are over graded rings. In particular, multiplication of scalars is not always possible, and so tensor product may not be always possible either. This is why we first introduce the notion of tensor product of vector spaces over graded rings. Then we give the detailed construction of disjunctions of SPHF.

<sup>8</sup> Here we consider  $\hat{\mathcal{X}}$  as  $\mathbb{Z}_p^n$ , for the sake of simplicity.

<sup>9</sup> Formal requirements can be found in Appendix B.2.

**Fig. 1.** Diverse Vector Space and Smooth Projective Hash Function (SPHF)

**Tensor Product of Vector Spaces over Graded Rings.** Let us very briefly recall notations for tensor product and adapt them to vector spaces over graded rings. Let  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  be two multiplicatively compatible sub-graded rings of  $\mathfrak{G}$ . Let  $V_1$  be a  $n_1$ -dimensional vector space over  $\mathfrak{G}_1$  and  $V_2$  be a  $n_2$ -dimensional vector space over  $\mathfrak{G}_2$ . Let  $(\mathbf{e}_{1,i})_{i=1}^{n_1}$  and  $(\mathbf{e}_{2,i})_{i=1}^{n_2}$  be bases of  $V_1$  and  $V_2$  respectively. Then the *tensor product*  $V$  of  $V_1$  and  $V_2$ , denoted  $V = V_1 \otimes V_2$  is the  $n_1 n_2$ -dimensional vector space over  $\mathfrak{G}$  generated by the free family  $(\mathbf{e}_{1,i} \otimes \mathbf{e}_{2,j})_{\substack{i=1, \dots, n_1 \\ j=1, \dots, n_2}}$ . The operator  $\otimes$  is bilinear, and if  $\mathbf{u} = \sum_{i=1}^{n_1} u_i \bullet \mathbf{e}_{1,i}$  and  $\mathbf{v} = \sum_{j=1}^{n_2} v_j \bullet \mathbf{e}_{2,j}$ , then:

$$\mathbf{u} \otimes \mathbf{v} = \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} (u_i \bullet v_j) \bullet (\mathbf{e}_{1,i} \otimes \mathbf{e}_{2,j}).$$

More generally, we can define the tensor product of two matrices  $M \in \mathfrak{G}_1^{k \times m}$  and  $M' \in \mathfrak{G}_2^{k' \times m'}$ ,  $T = M \otimes M' \in \mathfrak{G}^{kk' \times mm'}$  by

$$T_{(i-1)k'+i', (j-1)m'+j'} = M_{i,j} \bullet M'_{i',j'} \quad \text{for} \quad \begin{cases} i = 1, \dots, k, & i' = 1, \dots, k', \\ j = 1, \dots, m, & j' = 1, \dots, m'. \end{cases}$$

And if  $M \in \mathfrak{G}_1^{k \times m}$ ,  $M' \in \mathfrak{G}_2^{k' \times m'}$ ,  $N \in \mathfrak{G}_1^{m \times n}$  and  $N' \in \mathfrak{G}_2^{m' \times n'}$ , and if  $M \bullet N$  and  $M' \bullet N'$  are well-defined (i.e., are different than  $\perp$ , using the notation defined in Appendix B.1), then we have

$$(M \otimes M') \bullet (N \otimes N') = (M \bullet N) \otimes (M' \bullet N').$$

Finally, this definition can be extended to more than 2 vector spaces.

**Disjunctions of SPHFs.** In Fig. 2, we show the construction of the disjunction of two diverse vector spaces, over two multiplicatively sub-graded rings  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  of some graded ring  $\mathfrak{G}$ . In applications, we will often have  $\mathfrak{G}_1 = \mathbb{G}_1$  and  $\mathfrak{G}_2 = \mathbb{G}_2$  where  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$  is a bilinear group.

Diverse vector space  $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, n, k, \Gamma, \theta)$  **disjunction** of diverse vector spaces  $\mathcal{V}_1 = (\mathcal{X}_1, \mathcal{L}_1, \mathcal{R}_1, \mathfrak{G}_1, n_1, k_1, \Gamma_1, \theta_1)$  and  $\mathcal{V}_2 = (\mathcal{X}_2, \mathcal{L}_2, \mathcal{R}_2, \mathfrak{G}_2, n_2, k_2, \Gamma_2, \theta_2)$ :

- $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  are two multiplicatively compatible sub-graded rings of  $\mathfrak{G}$ ;
- $n = n_1 n_2$   $k = k_1 n_2 + n_1 k_2$ ;
- $\mathcal{X} = \mathcal{X}_1 \times \mathcal{X}_2$   $\mathcal{L} = (\mathcal{L}_1 \times \mathcal{X}_2) \cup (\mathcal{X}_1 \times \mathcal{L}_2)$
- $\Gamma = (\Gamma^{(1)} \otimes \text{Id}_{n_2} \quad \text{Id}_{n_1} \otimes \Gamma^{(2)})$   $\theta((C_1, C_2)) = \hat{C}_1 \otimes \hat{C}_2$ ;
- Witnesses  $\lambda$  for  $C = (C_1, C_2) \in \mathcal{L}$  (i.e., vectors  $\lambda \in \mathfrak{G}^k$  such that  $\mathcal{R}(C, \lambda) = 1$ ) are:

$$\lambda = \begin{cases} \begin{pmatrix} \lambda_1 \otimes \hat{C}_2 \\ \mathbf{0} \in \mathbb{Z}_p^{n_1 k_2} \end{pmatrix} & \text{when } \mathcal{R}_1(C_1, \lambda_1) = 1 \\ \begin{pmatrix} \mathbf{0} \in \mathbb{Z}_p^{k_1 n_2} \\ \hat{C}_1 \otimes \lambda_2 \end{pmatrix} & \text{when } \mathcal{R}_2(C_2, \lambda_2) = 1 \end{cases}$$

for any  $C = (C_1, C_2) \in \mathcal{X}$  and any  $\lambda \in \mathfrak{G}^n$ .

*Notation:* Due to the form of witnesses, we split the vector  $\gamma = \alpha \bullet \Gamma \in \mathfrak{G}^{k_1 n_2 + n_1 k_2}$  (of the resulting SPHF, with hashing key  $\text{hk} = \alpha \in \mathbb{Z}_p^{1 \times n_1 n_2}$ , see Fig. 1) in two parts:  $\gamma^{(1)} = \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) \in \mathfrak{G}^{1 \times k_1 n_2}$  which corresponds to the first  $k_1 n_2$  columns of  $\gamma$ , and  $\gamma^{(2)} = \alpha \bullet (\text{Id}_{n_1} \bullet \Gamma^{(2)}) \in \mathfrak{G}^{1 \times n_1 k_2}$  which corresponds to the last  $k_2 n_1$  columns of  $\gamma$ .

**Fig. 2.** Disjunction of Diverse Vector Spaces

Let us explain this construction. First, the rows of  $\Gamma$  generate the following subspace of  $\hat{\mathcal{X}} = \mathfrak{G}^{1 \times n} = \hat{\mathcal{X}}_1 \otimes \hat{\mathcal{X}}_2$ :

$$\hat{\mathcal{L}} = \langle (\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{X}}_2) \cup (\hat{\mathcal{X}}_1 \otimes \hat{\mathcal{L}}_2) \rangle,$$

where  $\hat{\mathcal{X}}_1 = \mathfrak{G}_1^{n_1}$ ,  $\hat{\mathcal{X}}_2 = \mathfrak{G}_2^{n_2}$ ,  $\hat{\mathcal{L}}_1$  is the subspace of  $\hat{\mathcal{X}}_1$  generated by the rows of  $\Gamma^{(1)}$  and  $\hat{\mathcal{L}}_2$  is the subspace of  $\hat{\mathcal{X}}_2$  generated by the rows of  $\Gamma^{(2)}$ . So this construction corresponds exactly to the one sketched in the Section 2.1.

Then, we need to prove that  $\mathcal{V}$  is really a diverse vector space, namely that  $C \in \mathcal{L}$  if and only if  $\theta(C) \in \hat{\mathcal{L}}$ . Clearly, if  $C = (C_1, C_2) \in \mathcal{L}$ , then  $\hat{C}_1 \in \hat{\mathcal{L}}_1$  or  $\hat{C}_2 \in \hat{\mathcal{L}}_2$  and so  $\hat{C} = \hat{C}_1 \otimes \hat{C}_2 \in \hat{\mathcal{L}}$ . Now, let us prove the converse. Let  $C = (C_1, C_2) \notin \mathcal{L}$ . So,  $\hat{C}_1 \notin \hat{\mathcal{L}}_1$  and  $\hat{C}_2 \notin \hat{\mathcal{L}}_2$ . Let  $H_1$  and  $H_2$  be supplementary vector spaces of  $\hat{\mathcal{L}}_1$  and  $\hat{\mathcal{L}}_2$  (in  $\hat{\mathcal{X}}_1$  and  $\hat{\mathcal{X}}_2$ , respectively). Then  $\hat{\mathcal{X}}_1$  is the direct sum of  $\hat{\mathcal{L}}_1$  and  $H_1$ , while  $\hat{\mathcal{X}}_2$  is the direct sum of  $\hat{\mathcal{L}}_2$  and  $H_2$ . Therefore,  $\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{X}}_2$  is the direct sum of  $\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{L}}_2$  and  $\hat{\mathcal{L}}_1 \otimes H_2$ , while  $\hat{\mathcal{X}}_1 \otimes \hat{\mathcal{L}}_2$  is the direct sum of  $\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{L}}_2$  and  $H_1 \otimes \hat{\mathcal{L}}_2$ . So finally,  $\hat{\mathcal{L}}$  is the direct sum of  $\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{L}}_2$ ,  $\hat{\mathcal{L}}_1 \otimes H_2$  and  $H_1 \otimes \hat{\mathcal{L}}_2$ ; and  $H_1 \otimes H_2$  is a supplementary of  $\hat{\mathcal{L}}$ . Since  $0 \neq \hat{C}_1 \otimes \hat{C}_2 \in H_1 \otimes H_2$ ,  $\theta(C) = \hat{C}_1 \otimes \hat{C}_2 \notin \hat{\mathcal{L}}$ .

Besides showing the correctness of the construction, this proof helps to better understand the structure of  $\hat{\mathcal{L}}$ . In particular, it shows that  $\hat{\mathcal{L}}$  has dimension  $l_1 l_2 + (n_1 - l_1) l_2 + l_1 (n_2 - l_2) = l_1 n_2 + n_1 l_2 - l_1 l_2$ , if  $\hat{\mathcal{L}}_1$  has dimension  $l_1$  and  $\hat{\mathcal{L}}_2$  has dimension  $l_2$ . If the rows of  $\Gamma^{(1)}$  and  $\Gamma^{(2)}$  are linearly independent,  $l_1 = k_1$  and  $l_2 = k_2$ ,  $\hat{\mathcal{L}}$  has dimension  $k_1 n_2 + n_1 k_2 - k_1 k_2$ , which is less than  $k_1 n_2 + n_1 k_2$ , the number of rows of  $\Gamma$ . Therefore the rows of  $\Gamma$  are never linearly independent. Actually, this last result can directly be proven by remarking that if  $\hat{C}_1 \in \hat{\mathcal{L}}_1$  and  $\hat{C}_2 \in \hat{\mathcal{L}}_2$ , then  $\hat{C}_1 \otimes \hat{C}_2 \in (\hat{\mathcal{L}}_1 \otimes \hat{\mathcal{X}}_2) \cap (\hat{\mathcal{X}}_1 \otimes \hat{\mathcal{L}}_2)$ . For the sake of completeness, detailed and concrete equations are detailed in Appendix B.3.

## 5 One-Time Simulation-Sound NIZK from Disjunctions of SPHFs

In this section, we present our construction of NIZK and one-time simulation-sound NIZK from disjunctions of SPHFs. The latter requires the use of a new notion: 2-smooth projective hash functions. We suppose the reader is familiar with NIZK and one-time simulation-sound NIZK. Formal definitions can be found in Appendix A.5.

### 5.1 NIZK from Disjunctions of SPHF

**Construction.** In Fig. 3, we show how to construct a NIZK for any family of languages  $\mathcal{L}_1$  such that there exist two diverse vector spaces  $\mathcal{V}_1 = (\mathcal{X}_1, \mathcal{L}_1, \mathcal{R}_1, \mathfrak{G}_1, n_1, k_1, \Gamma^{(1)}, \theta_1)$  and  $\mathcal{V}_2 = (\mathcal{X}_2, \mathcal{L}_2, \mathcal{R}_2, \mathfrak{G}_2, n_2, k_2, \Gamma^{(2)}, \theta_2)$  over two multiplicatively-compatible sub-graded rings  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  of some graded ring  $\mathfrak{G}$ , such that the second diverse vector space corresponds to a hard subset membership language. In particular, this construction works for any diverse vector space  $\mathcal{V}_1$  where  $\mathfrak{G}_1 = \mathbb{G}_1$  is a cyclic group of some bilinear group  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$ , where SXDH holds, by using as  $\mathcal{V}_2$  the discrete vector space for DDH over  $\mathbb{G}_2$  (Example 1).

**NIZK** for  $\mathcal{V}_1 = (\mathcal{X}_1, \mathcal{L}_1, \mathcal{R}_1, \mathfrak{G}_1, n_1, k_1, \Gamma_1, \theta_1)$ , using  $\mathcal{V}_2 = (\mathcal{X}_2, \mathcal{L}_2, \mathcal{R}_2, \mathfrak{G}_2, n_2, k_2, \Gamma_2, \theta_2)$ , with  $\mathcal{L}_2$  a hard subset membership language:

- $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, n, k, \Gamma, \theta)$  disjunction of  $\mathcal{V}_1$  and  $\mathcal{V}_2$ ;
- Setup: computes  $\text{hk} = \alpha \stackrel{\$}{\leftarrow} \mathbb{Z}_p^{1 \times n}$ ,  $\text{hp} = \gamma = (\gamma^{(1)}, \gamma^{(2)}) = \alpha \bullet \Gamma$  (with  $\gamma^{(1)} = \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2})$  and  $\gamma^{(2)} = \alpha \bullet (\text{Id}_{n_1} \bullet \Gamma^{(2)})$ , see Fig. 2), and outputs trapdoor  $\mathcal{T} := \text{hk}$ , and CRS  $\sigma := (\text{crs}_2, \text{hp})$ ;
- Proof  $\pi$  of  $C_1 \in \mathcal{L}_1$  with witness  $\lambda_1 \in \mathfrak{G}^{k_1}$ :
 
$$\pi := \gamma^{(1)} \bullet (\lambda_1 \otimes \text{Id}_{n_2}) \in \mathfrak{G}_1^{1 \times n_2};$$
- Verification of proof  $\pi$  for  $C_1$ :
 
$$\pi \bullet \Gamma^{(2)} \stackrel{?}{=} \gamma^{(2)} \bullet (\hat{C}_1 \otimes \text{Id}_{k_2}), \tag{1}$$
- Simulation of proof  $\pi$  for  $C_1$  knowing  $\mathcal{T} = \text{hk}$ :
 
$$\pi := \alpha \bullet (\hat{C}_1 \otimes \text{Id}_{n_2}).$$

Fig. 3. NIZK from Disjunctions of Diverse Spaces

The proof  $\pi$  of a word  $C_1$  can just be seen as the hash values of rows<sup>10</sup> of  $\hat{C}_1 \otimes \text{Id}_{n_2}$ . Let us now show that our NIZK is complete, zero-knowledge and sound.

**Completeness.** If the proof  $\pi$  has been generated correctly, the left hand side of the verification equation (Eq. (1)) is equal to

$$\begin{aligned} \gamma^{(1)} \bullet (\lambda_1 \otimes \text{Id}_{n_2}) \bullet \Gamma^{(2)} &= (\alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2})) \bullet (\lambda_1 \otimes \text{Id}_{n_2}) \bullet (\text{Id}_1 \otimes \Gamma^{(2)}) \\ &= \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) \bullet ((\lambda_1 \bullet \text{Id}_1) \otimes (\text{Id}_{n_2} \bullet \Gamma^{(2)})) \\ &= \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) \bullet (\lambda_1 \otimes \Gamma^{(2)}) \\ &= \alpha \bullet ((\Gamma^{(1)} \bullet \lambda_1) \otimes (\text{Id}_{n_2} \bullet \Gamma^{(2)})), \end{aligned}$$

while the right hand side is always equal to:

$$\gamma^{(2)} \bullet (\hat{C}_1 \otimes \text{Id}_{k_2}) = \alpha \bullet (\text{Id}_{n_1} \otimes \Gamma^{(2)}) \bullet (\hat{C}_1 \otimes \text{Id}_{k_2}) = \alpha \bullet ((\text{Id}_{n_1} \bullet \hat{C}_1) \otimes (\Gamma^{(2)} \bullet \text{Id}_{k_2})),$$

which is the same as the left hand side, since  $\Gamma^{(1)} \bullet \lambda_1 = \text{Id}_{n_1} \bullet \hat{C}_1$  and  $\text{Id}_{n_2} \bullet \Gamma^{(2)} = \Gamma^{(2)} \bullet \text{Id}_{k_2}$ . Hence the *completeness*. Another way to see it, is that the row  $i_2$  of the right hand side is the hash value of “ $(\hat{C}_1, \Gamma^{(2)} \bullet e_{2, i_2})$ ” computed using the witness  $\lambda_2 = e_{2, i_2}$ , while the row  $i_2$  of the left hand side is this hash value computed using the witness  $\lambda_1$ .

**Zero-Knowledge.** The (perfect) unbounded *zero-knowledge* property comes from the fact that the normal proof  $\pi$  for  $C_1 \in \mathcal{L}_1$  with witness  $\lambda_1$  is:

$$\pi = \gamma^{(1)} \bullet (\lambda_1 \otimes \text{Id}_{n_2}) = \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) \bullet (\lambda_1 \otimes \text{Id}_{n_2}) = \alpha \bullet ((\Gamma^{(1)} \bullet \lambda_1) \otimes (\text{Id}_{n_2} \bullet \text{Id}_{n_2})),$$

<sup>10</sup> This is not quite accurate, since rows of  $\hat{C}_1 \otimes \text{Id}_{n_1}$  are not words in  $\mathcal{X}$  but in  $\hat{\mathcal{X}}$ . But to give intuition, we will often make this abuse of notation.

which is equal to the simulated proof for  $C_1$ , as  $\hat{C}_1 = \Gamma^{(1)} \bullet \lambda_1$  and  $\text{Id}_{n_2} \bullet \text{Id}_{n_2} = \text{Id}_{n_2}$ .

**Soundness.** It remains to prove the soundness property, under the hard subset membership of  $\mathcal{L}_2$ . We just need to show that if the adversary is able to generate a valid proof  $\pi$  for a word  $C_1 \notin \mathcal{L}_1$ , then we can use  $\pi$  to check if a word  $C_2$  is in  $\mathcal{L}_2$  or not. More precisely, let  $C_2 \in \mathcal{X}_2$ , let  $H$  be the hash value of  $(C_1, C_2)$  computed using  $\text{hk}$ , and let us define  $H' := \pi \bullet \hat{C}_2$ .

On the one hand, if  $C_2 \in \mathcal{L}_2$ , there exists a witness  $\lambda_2$  such that  $\hat{C}_2 = \Gamma^{(2)} \bullet \lambda_2$  and so, thanks to Eq. (1):

$$H' = \pi \bullet \Gamma^{(2)} \bullet \lambda_2 = \gamma^{(2)} \bullet (\hat{C}_1 \otimes \text{Id}_{k_2}) \bullet \lambda_2 = \gamma^{(2)} \bullet (\hat{C}_1 \otimes \lambda_2) = H,$$

the last equality coming from the correctness of the SPHF and the fact the last-but-one expression is just the hash value of  $(C_1, C_2)$  computed using  $\text{ProjHash}$  and witness  $\lambda_2$ .

On the other hand, if  $C_2 \notin \mathcal{L}_2$ , then  $(C_1, C_2) \notin \mathcal{L}$ . So  $H$  looks completely random by smoothness and the probability that  $H' = H$  is at most  $1/|\Pi|$ .

**Toward One-Time Simulation Soundness.** The previous proof does not work anymore if the adversary is allowed to get even one single simulated proof of a word  $C_1 \notin \mathcal{L}_1$ . Indeed, in this case, the smoothness does not hold anymore, in the above proof of soundness. That is why we need a stronger form of smoothness for SPHF, called 2-smoothness.

## 5.2 2-Smooth Projective Hash Functions

**Definition.** In order to define the notion of 2-smoothness, let us first introduce the notion of tag-SPHF. A *tag-SPHF* is similar to an SPHF except that  $\text{Hash}$  and  $\text{ProjHash}$  now take a new input, called a tag  $\text{tag} \in \text{Tags}$ . Similarly a *tag diverse vector space* is a diverse vector space where the function  $\theta$  also takes as input a tag  $\text{tag} \in \mathbb{Z}_p$ . The vector  $\lambda$  is now allowed to depend on  $\text{tag}$ , but the matrix  $\Gamma$  is independent of  $\text{tag}$ .

A 2-smooth SPHF is a tag-SPHF for which the hash value of a word  $C \in \mathcal{X}$  for a tag  $\text{tag}$  looks random even if we have access to the hash value of another word  $C' \in \mathcal{X}$  for a different tag  $\text{tag}' \neq \text{tag}$ . Formally, a tag-SPHF is perfectly 2-smooth, if for any  $\text{crs}$ , any  $C' \in \mathcal{X}$ , any distinct tags  $\text{tag}, \text{tag}'$ , and any  $C \notin \mathcal{L}_{\text{crs}}$ , the following two distributions are identical:

$$\left\{ (\text{hp}, H', H) \left| \begin{array}{ll} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); & \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ H' \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C', \text{tag}')); & H \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C, \text{tag})) \end{array} \right. \right\}$$

$$\left\{ (\text{hp}, H', H) \left| \begin{array}{ll} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); & \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ H' \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C', \text{tag}')); & H \xleftarrow{\$} \Pi \end{array} \right. \right\}.$$

A weaker (statistical instead of perfect) definition is proposed in Appendix B.4. The 2-smoothness property is similar to the 2-universality property in [CS02]. There are however two minor differences, the first being the existence of an explicit tag, and the second being that the hash value of a word outside the language is supposed to be uniformly random instead of just having some entropy. This slightly simplifies its usage in our constructions, in our opinion.

**Canonical Construction from Diverse Vector Spaces.** Let  $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, n, k, \Gamma, \theta)$  be a diverse vector space. If we set  $\tilde{n} = 2n$ ,  $\tilde{k} = 2k$ , and:

$$\tilde{\Gamma} = \begin{pmatrix} \Gamma & 0 \\ 0 & \Gamma \end{pmatrix} \quad \tilde{\lambda} = \begin{pmatrix} \lambda \\ \text{tag} \bullet \lambda \end{pmatrix} \quad \tilde{\theta}(C, \text{tag}) = \begin{pmatrix} \hat{C} \\ \text{tag} \bullet \hat{C} \end{pmatrix},$$

where  $\tilde{\lambda}$  is the witness for a word  $C \in \mathcal{L}$  and a tag  $\text{tag}$ , then  $\tilde{\mathcal{V}} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, \tilde{n}, \tilde{k}, \tilde{\Gamma}, \tilde{\theta})$  is a 2-smooth diverse vector space. It is clear that  $C \in \mathcal{L}$  if and only if  $\tilde{C} = \tilde{\theta}(C, \text{tag})$  is a linear combination of rows of  $\tilde{\Gamma}$ .

To prove the 2-smoothness property, let  $C' \in \mathcal{X}$  and  $C \in \mathcal{X} \setminus \mathcal{L}$ , and let  $\text{tag}'$  and  $\text{tag}$  be two distinct tags. We have

$$\tilde{C}' = \begin{pmatrix} \hat{C}' \\ \text{tag}' \bullet \hat{C}' \end{pmatrix} \quad \text{and} \quad \tilde{C} = \begin{pmatrix} \hat{C} \\ \text{tag} \bullet \hat{C} \end{pmatrix}.$$

We just need to prove that  $\tilde{C}$  is not in the subspace generated by the rows of  $\Gamma$  and  $\tilde{C}'$ , or in other words that it is not in  $\mathcal{L}' = \langle \mathcal{L} \cup \{\tilde{C}'\} \rangle$ . Indeed, in that case,  $H'$  could just be seen as a part of the projection key for the language  $\mathcal{L}'$ , and by smoothness, we get that  $H$  looks uniformly random.

So it remains to prove that linear independence of  $\tilde{C}$ . By contradiction, let us suppose there exists  $\tilde{\lambda} \in \mathbb{Z}_p^{2k}$  and  $\mu$  such that:

$$\tilde{C} = \begin{pmatrix} \hat{C} \\ \text{tag} \bullet \hat{C} \end{pmatrix} = \tilde{\Gamma} \bullet \tilde{\lambda} + \tilde{C}' \bullet \mu = \begin{pmatrix} \Gamma & 0 \\ 0 & \Gamma \end{pmatrix} \bullet \tilde{\lambda} + \begin{pmatrix} \hat{C}' \\ \text{tag}' \bullet \hat{C}' \end{pmatrix} \bullet \mu.$$

Therefore  $\tilde{C} + \mu \bullet \tilde{C}'$  and  $\text{tag} \bullet \tilde{C} + \text{tag}' \bullet \mu \bullet \tilde{C}'$  are both linear combination of rows of  $\Gamma$ , and so is

$$\text{tag}' \bullet (\tilde{C} + \mu \bullet \tilde{C}') + (\text{tag} \bullet \tilde{C} + \text{tag}' \bullet \mu \bullet \tilde{C}') = (\text{tag}' - \text{tag}) \bullet \tilde{C}.$$

As  $\text{tag}' - \text{tag} \neq 0$ , this implies that  $\tilde{C}$  is also a linear combination of rows of  $\Gamma$ , hence  $C \in \mathcal{L}$ , which is not the case.

### 5.3 One-Time Simulation-Sound Zero-Knowledge Arguments from SPHF

Let us now replace the first diverse vector space by its canonical 2-smooth version in the NIZK construction of Section 5.1. The resulting construction is a one-time simulation-sound NIZK, if  $\hat{C}_1$  is computed as  $\theta_1(C_1, \text{tag})$  where  $\text{tag}$  is the hash value of  $(C_1, \ell)$  under some collision-resistant hash function  $\mathcal{H}$ :  $\text{tag} = \mathcal{H}((C_1, \ell))$ .

Completeness and perfect zero-knowledge can be proven the same way. It remains to prove the one-time simulation soundness. The proof is similar to the one in Section 5.1, except for the final step: proving that the hash value  $H$  of  $(C_1, C_2)$  with  $\text{tag} = \mathcal{H}((C_1, \ell))$  looks random even if the adversary sees a simulated NIZK  $\pi'$  for a word  $C'_1 \in \mathcal{X}_1$  and label  $\ell'$ .

We first remark that the tag  $\text{tag}'$  can be supposed distinct from the tag  $\text{tag}$  for the NIZK  $\pi$  created by the adversary, thanks to the collision-resistance of  $\mathcal{H}$ . We recall that  $\pi'$  is the hash values of the rows of  $\hat{C}'_1 \otimes \text{Id}_{n_2}$ . So to prove that the hash value of  $(C_1, C_2)$  with tag  $\text{tag}$  looks random even with access to  $\pi'$ , we just need to remark that  $\hat{C}_1 \otimes \hat{C}_2$  is linearly independent of rows of  $\Gamma$  and  $\hat{C}'_1 \otimes \text{Id}_{n_2}$ . The proof is similar to the proof of 2-smoothness.

*Remark 7.* It would be easy to extend this construction to handle  $N$ -time simulation-sound NIZK, for any constant  $N$ . The NIZK CRS  $\sigma$  size would just be  $N$  times larger compared to the NIZK construction of Section 5.1, and the proof size would remain constant.

### 5.4 Concrete Instantiation

If  $\mathcal{V}_1$  is a diverse vector space over  $\mathbb{G}_1$  and  $\mathcal{V}_2$  is the diverse vector space for DDH in  $\mathbb{G}_2$ , where  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$  is a bilinear group where DDH is hard in  $\mathbb{G}_2$ , then we get a NIZK and a one-time simulation sound NIZK whose proof is composed of only  $n_2 = 2$  group elements in  $\mathbb{G}_1$ .

More generally, we can use as  $\mathcal{V}_2$ , any diverse vector space from any MDDH assumption [EHK<sup>+</sup>13]. In particular, for  $\kappa$ -Lin, we would get:  $\mathcal{X}_2 = \hat{\mathcal{X}}_2 = \mathbb{G}_2^{\kappa+1}$ ,  $\text{crs}_2 = (g_2, \zeta_1, \dots,$

$\zeta_\kappa) \stackrel{s}{\leftarrow} \mathbb{G}_2^{\kappa+1}$ ,  $\theta_2$  is the identity function and  $\hat{\mathcal{L}}_2 = \mathcal{L}_2$  is defined by the following matrix:

$$\Gamma_2 = \begin{pmatrix} \zeta_1 & 1 & \dots & 1 \\ 1 & \zeta_2 & \dots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \dots & \zeta_\kappa \\ g_2 & g_2 & \dots & g_2 \end{pmatrix},$$

where 1 is the element  $g_2^0 \in \mathbb{G}_2$ . A word  $C_2 = \hat{C}_2 = (\hat{C}_{2,1}, \dots, \hat{C}_{2,\kappa+1})^\top \in \mathcal{X}_2$  is in  $\mathcal{L}_2$  if and only if  $(\zeta_1, \dots, \zeta_\kappa, \hat{C}_{2,1}, \dots, \hat{C}_{2,\kappa}, \hat{C}_{2,\kappa+1})$  is a  $\kappa$ -Lin-tuple (see Section 3.4). This yields a proof consisting of only  $n_2 = \kappa + 1$  group elements, under  $\kappa$ -Lin. The DDH case corresponds to  $\kappa = 1$ .

Languages handled are exactly languages for which there exists such a diverse vector space  $\mathcal{V}_1$  over  $\mathbb{G}_1$ . That corresponds to languages handled by Jutla and Roy NIZK [JR13], which they call linear subspaces (assuming  $\theta$  is the identity function), if we forget the fact that in [JR13], it is supposed that  $\text{crs}$  can be generated in such a way that discrete logarithms of  $\Gamma$  is known (that is what they call *witness-samplable* languages). That encompasses DDH,  $\kappa$ -Lin, and languages of ElGamal, Cramer-Shoup or similar ciphertexts whose plaintexts verify some linear system of equations, as already shown in [BBC<sup>+</sup>13]. Concrete comparison with previous work can be found in Section 7.3.

### 5.5 Application: Threshold Cramer-Shoup-like Encryption Scheme

The Cramer-Shoup public-key encryption scheme [CS98] is one of the most efficient IND-CCA encryption schemes with a proof of security in the standard model. We remark here that, if we replace the last part of a Cramer-Shoup ciphertext (the 2-universal projective hash proof or  $w$  in our notations in Appendix A.3) by a one-time simulation-sound NIZK on the DDH language, we can obtain an IND-CCA scheme supporting efficient threshold decryption. Intuitively, this comes from the fact that the resulting scheme becomes “publicly verifiable”, in the sense that, after verifying the NIZK (which is publicly verifiable), one can obtain the underlying message via “simple” algebraic operations which can easily be “distributed”.

Previous one-time simulation-sound NIZK were quite inefficient and the resulting scheme would have been very inefficient compared to direct constructions of threshold IND-CCA encryption schemes. However, in our case, our new one-time simulation-sound NIZK based on disjunctions of SPHF only adds one group element to the ciphertext (compared to original Cramer-Shoup encryption scheme; see Appendix D.1 for details). In addition, both the encryption and the decryption algorithms only require to perform operations in the first group  $\mathbb{G}_1$ . A detailed comparison is given in Section 7.4, where we also introduce a more efficient version of that threshold encryption scheme, for which the ciphertexts have the same size as the ciphertexts of the original Cramer-Shoup encryption scheme.

## 6 Pseudo-Random Projective Hash Functions and Disjunctions

In this section, we sometimes make explicit use of  $\text{crs}$  (or  $\text{crs}_1$ , or  $\text{crs}_2$ ), the language parameters of the diverse vector space  $\mathcal{V}$  (respectively of  $\mathcal{V}_1$ , and  $\mathcal{V}_2$ ), to provide clearer definitions. We recall that we suppose there exists an algorithm  $\text{Setup}_{\text{crs}}$  which can generate  $\text{crs}$  together with a trapdoor  $\mathcal{T}_{\text{crs}}$ . Contrary to construction in previous sections, where  $\mathcal{T}_{\text{crs}} = \perp$ , the security of the constructions in this section will depend on some properties of  $\mathcal{T}_{\text{crs}}$ .

### 6.1 Pseudo-Randomness

**Definition.** An SPHF is said to be *pseudo-random*, if the hash value of a random word  $C$  in  $\mathcal{L}_{\text{crs}}$  looks random to an adversary only knowing the projection key  $\text{hp}$  and ignoring the hashing

$\text{Exp}^{\text{ps-rnd-}b}(\mathcal{A}, \mathfrak{R})$ $(\text{crs}, \mathcal{T}_{\text{crs}}) \xleftarrow{\$} \text{Setup}_{\text{crs}}(1^{\mathfrak{R}})$ $\text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs})$ $\text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs})$ $C \xleftarrow{\$} \mathcal{L}_{\text{crs}}$ <b>if</b> $b = 0$ <b>then</b> $H \leftarrow \text{Hash}(\text{hk}, \text{crs}, C)$ <b>else</b> $H \xleftarrow{\$} \Pi$ <b>return</b> $\mathcal{A}(\text{crs}, C, \text{hp}, H)$	$\text{Exp}^{\text{mixed-ps-rnd-}b}(\mathcal{A}, \mathfrak{R})$ $(\text{crs} = (\text{crs}_1, \text{crs}_2), (\mathcal{T}_{\text{crs}_1}, \mathcal{T}_{\text{crs}_2})) \xleftarrow{\$} \text{Setup}_{\text{crs}}(1^{\mathfrak{R}})$ $\text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs})$ $C_2 \xleftarrow{\$} \mathcal{L}_{2, \text{crs}_2}$ $(C_1, \text{st}) \xleftarrow{\$} \mathcal{A}(\text{crs}, \mathcal{T}_{\text{crs}_1}, \text{hp}, C_2); C \leftarrow (C_1, C_2)$ <b>if</b> $b = 0$ <b>or</b> $C_1 \in \mathcal{L}_{1, \text{crs}_1}$ <b>then</b> $H \leftarrow \text{Hash}(\text{hk}, \text{crs}, C)$ <b>else</b> $H \xleftarrow{\$} \Pi$ <b>return</b> $\mathcal{A}(\text{st}, H)$
---	---

**Fig. 4.** Experiments  $\text{Exp}^{\text{ps-rnd-}b}$  and  $\text{Exp}^{\text{mixed-ps-rnd-}b}$  for pseudo-randomness and mixed pseudo-randomness

key  $\text{hk}$  and a witness for the word  $C$ . More precisely, this property is defined by the experiments  $\text{Exp}^{\text{ps-rnd-}b}$  depicted in Fig. 4. Contrary to smoothness, this property is computational. A projective hashing function which is pseudo-random is called a PrPHF. A PrPHF is not necessarily smooth.

**Link with Hard Subset Membership Languages.** It is easy to see that an SPHF over a hard subset membership family of languages is pseudo-random. This yields a way to create PrPHF under DDH using Example 1. However, this is inefficient since, in this case  $\mathcal{X}$  has dimension 2, while we would prefer to have  $\mathcal{X}$  of dimension 1. Actually, since for hard subset membership languages,  $\mathcal{L}_{\text{crs}} \neq \mathcal{X}$ , any SPHF based on diverse vector space for these languages is such that  $\mathcal{X}$  has dimension at least 2. More generally, as shown in Section 5.4, for a hard subset membership language based on  $\kappa$ -Lin,  $\mathcal{X} = \mathbb{G}^{1 \times (\kappa+1)}$  and  $\mathcal{L}_{\text{crs}}$  has dimension  $\kappa$ . That is why we introduce another way to construct PrPHF, still based on diverse vector spaces, but not using hard subset membership languages.

## 6.2 Canonical PrPHF under $\kappa$ -Lin

Let us construct a diverse vector space  $(\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathbb{G}, n, k, \Gamma, \theta)$  which yields a pseudo-random SPHF under  $\kappa$ -Lin in the cyclic group  $\mathbb{G}$ .

We set  $\mathcal{X} = \mathcal{L}_{\text{crs}} = \{\perp\}$  and  $\hat{\mathcal{X}} = \hat{\mathcal{L}}_{\text{crs}} = \mathbb{G}^{\kappa}$ . For DDH = 1-Lin, we get a PrPHF with  $\mathcal{X}$  of dimension 1, which is the best we can do using diverse vector spaces. Even though the resulting projective hash function will be smooth, the smoothness property is completely trivial, since  $\mathcal{L}_{\text{crs}} \setminus \mathcal{X}$  is empty, and does not imply the pseudo-randomness property. We will therefore need to manually prove the pseudo-randomness.

The “language” is defined by  $\text{crs} = (\zeta_1, \dots, \zeta_{\kappa}) \xleftarrow{\$} \mathbb{G}^{\kappa}$  and the PrPHF by:

$$\Gamma := \begin{pmatrix} \zeta_1 & 0 & \dots & 0 \\ 0 & \zeta_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \zeta_{\kappa} \end{pmatrix} \in \mathbb{G}^{\kappa \times \kappa} \quad \lambda := \begin{pmatrix} \hat{\zeta}_1 \\ \hat{\zeta}_2 \\ \vdots \\ \hat{\zeta}_{\kappa} \end{pmatrix} \in \mathbb{Z}_p^{\kappa} \quad \theta(\perp) := \begin{pmatrix} g \\ g \\ \vdots \\ g \end{pmatrix} \in \mathbb{G}^{\kappa}$$

$$\text{hk} := \alpha \xleftarrow{\$} \mathbb{Z}_p^{1 \times \kappa}$$

$$\text{hp} := (\gamma_1, \dots, \gamma_{\kappa})^{\top} = (\zeta_1^{\alpha_1}, \dots, \zeta_{\kappa}^{\alpha_{\kappa}})^{\top} \in \mathbb{G}^{\kappa}$$

$$H := \prod_{i=1}^n g^{\alpha_i} = g^{\sum_{i=1}^n \alpha_i} = \prod_{i=1}^n \gamma_i^{\hat{\zeta}_i} =: H',$$

where  $\lambda$  is the witness for  $C = \perp$ , with  $\zeta_i = g^{1/\hat{\zeta}_i}$ . The pseudo-randomness directly comes from the hardness of  $\kappa$ -Lin.

## 6.3 Disjunction of an SPHF and a PrPHF

Let  $\mathcal{V}_1 = (\mathcal{X}_1, \mathcal{L}_1, \mathcal{R}_1, \mathfrak{G}_1, n_1, k_1, \Gamma^{(1)}, \theta_1)$  and  $\mathcal{V}_2 = (\mathcal{X}_2, \mathcal{L}_2, \mathcal{R}_2, \mathfrak{G}_2, n_2, k_2, \Gamma^{(2)}, \theta_2)$  be two diverse vector spaces over two multiplicatively sub-graded rings  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  of some graded ring

$\mathfrak{G}$ . Let  $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathfrak{G}, n, k, \Gamma, \theta)$  be the vector space corresponding to the disjunction of the two previous languages. We have already seen that this vector space corresponds to a smooth projective hash function.

But, if the second language is the canonical PrPHF under  $\kappa$ -Lin, the smoothness brings nothing, since  $\mathcal{X} = \mathcal{L}$ . Therefore, we need to prove a stronger property called *mixed pseudo-randomness*.

**Definition of Mixed Pseudo-Randomness.** The resulting SPHF is said mixed pseudo-random, if the hash value of a word  $C = (C_1, C_2)$  looks random to the adversary, when  $C_1 \notin \mathcal{L}_1$  is chosen by the adversary, while  $C_2$  is chosen at random in  $\mathcal{L}_2$ . More precisely, the mixed pseudo-randomness property is defined by the experiments  $\text{Exp}^{\text{mixed-ps-rnd-b}}$  depicted in Fig. 4.

**Proof of Mixed Pseudo-Randomness.** The proof of mixed pseudo-randomness is actually close to the one for computational soundness of trapdoor smooth projective functions in [BBC<sup>+</sup>13]. It requires that  $\mathcal{T}_{\text{crs}_1}$  contains enough information to be able to compute the discrete logarithm of elements of  $\Gamma^{(1)}$ , denoted  $\mathfrak{L}(\Gamma^{(1)})$ .

The proof reduces the pseudo-randomness property to the mixed pseudo-randomness property. The detailed proof is quite technical and can be found in Appendix C. Basically, we choose a random hashing key  $\varepsilon$  and we randomize it using a basis of the kernel of  $\mathfrak{L}(\Gamma^{(1)})$  and projection keys given by the pseudo-randomness game (for some fixed word  $C_2$ , using a hybrid method). Then we show how to compute from that, a valid projection key hp for the language of the disjunction together with a hash value  $H$  of  $(C_1, C_2)$ , for  $C_1 \notin \mathcal{L}_1$ . This value  $H$  is the correct hash value, if the hash values of  $C_2$ , given by the challenger of the hybrid pseudo-randomness game, were valid; and it is a random value, otherwise. That proves that an adversary able to break the mixed pseudo-randomness property also breaks the pseudo-randomness property.

## 7 One-Time Simulation-Sound NIZK from Disjunctions of an SPHF and a PrPHF

### 7.1 NIZK from Disjunctions of an SPHF and a PrPHF

The construction is identical to the one in Section 5.1, except that the second diverse vector space  $\mathcal{V}_2$  is just supposed to be a PrPHF, and no more supposed to be related to a hard subset membership language  $\mathcal{L}_2$ . However, we suppose that the disjunction of  $\mathcal{V}_1$  and  $\mathcal{V}_2$  yields a mixed pseudo-random SPHF, which is the case if  $\mathcal{T}_{\text{crs}}$  contains enough information to compute the discrete logarithm of elements of  $\Gamma^{(1)}$ .

Completeness and zero-knowledge can be proven exactly in the same way. It remains therefore to prove the soundness property, under the mixed pseudo-randomness. The proof is very similar to the one in Section 5.1: if  $\pi$  is a proof of some word  $C_1 \notin \mathcal{L}_1$ , then it is possible to compute the hash value of any word  $(C_1, C_2)$  with  $C_2 \in \mathcal{L}_2$  as  $H' := \pi \bullet \hat{C}_2$ . This comes from the fact that if  $C_2 \in \mathcal{L}_2$ , then there exists  $\lambda_2$  such that  $\hat{C}_2 = \lambda_2 \bullet \Gamma^{(2)}$ , hence:

$$H' = \pi \bullet \Gamma^{(2)} \bullet \lambda_2 = \gamma^{(2)} \bullet (\hat{C}_1 \otimes \text{Id}_{k_2}) \bullet \lambda_2 = \gamma^{(2)} \bullet (\hat{C}_1 \otimes \lambda_2),$$

which is the hash value of  $(C_1, C_2)$  computed using ProjHash and witness  $\lambda_2$ . But the mixed pseudo-randomness property ensures that this value looks uniformly random when  $C_2$  is chosen randomly in  $\mathcal{L}_2$ . That proves the soundness property.

### 7.2 One-Time Simulation-Sound NIZK

Unfortunately, for the one-time simulation-sound variant, this is not as easy: the construction in Section 5.3 seems difficult (if at all possible) to prove sound. The main problem is that the security proof of mixed pseudo-randomness is not statistical, so we do not know  $\text{hk} = \alpha$ , but only some representation of  $\alpha$ , which does not allow computing the proof  $\pi'$  of a word  $C'_1$  for a

tag  $\text{tag}_{C'_1}$ . Directly adapting the proof with a 2-smooth  $\mathcal{V}_1$  would require to choose from the beginning  $\pi'$  (as is chosen  $\text{hp}$  from the beginning), but that is not possible since  $C'_1$  and  $\text{tag}'$  (the tag for  $C'_1$ ) are not known at the beginning of the game.

Our solution is to use the tag bit-by-bit. So we just need to guess which bit is different between  $\text{tag}_{C_1}$  and  $\text{tag}_{C'_1}$ . This idea is inspired from [CW13]. Details can be found in Appendix B.5.

### 7.3 Concrete Instantiation and Comparison with Previous Work

If  $\mathcal{V}_1$  is a diverse vector space over  $\mathbb{G}_1$  (for which  $\mathcal{T}_{\text{crs}_1}$  gives enough information to compute the discrete logarithm of  $\Gamma^{(1)}$ ) and  $\mathcal{V}_2$  is the canonical PrPHF under DDH in Section 6.2, where  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$  is a bilinear group where DDH is hard in  $\mathbb{G}_2$ , then we get an NIZK and a one-time simulation sound NIZK whose proof is composed of only  $n_2 = 1$  group element in  $\mathbb{G}_1$ . More generally, if  $\mathcal{V}_2$  is canonical PrPHF under  $\kappa$ -Lin, then the proof consists of only  $\kappa$  group elements, one less than our first construction in Section 5.4. However, this encompasses slightly fewer languages than this first construction, due to the restriction on  $\mathcal{L}_1$  and  $\mathcal{T}_{\text{crs}_1}$ . More precisely, our NIZK handles the same languages as Jutla-Roy NIZK in [JR13, JR14].

Table 1 compares NIZK for linear subspaces as Jutla and Roy call it in [JR13], i.e., any language over  $\mathbb{G}_1$  (first group of some bilinear group) for which there exists a diverse vector space  $\mathcal{V}_1$  (assuming  $\theta$  is the identity function and a witness is  $\lambda \in \mathbb{Z}_p^k$ ). Some of the entries of this table were derived from [JR14] and from [LPJY14]. The DDH (in  $\mathbb{G}_2$ ) variant requires asymmetric bilinear groups, while the  $\kappa$ -Lin variant for  $\kappa \geq 2$  could work on symmetric bilinear groups.

First of all, as far as we know, our one-time simulation-sound NIZK is the most efficient such NIZK with a constant-size proof: the single-theorem relatively-sound construction of Libert et al. [LPJY14] is weaker than our one-time simulation-sound NIZK and requires at least one group element more in the proof, while their universal simulation-sound construction is much more inefficient. A direct application of our construction is our efficient structure-preserving threshold IND-CCA encryption scheme, under DDH.

Second, the DLin version of our NIZK in Section 5.1 is similar to the one by Libert et al. [LPJY14], but our DLin version of our NIZK in Section 7.1 is more efficient (the proof has 2 group elements instead of 3). Furthermore, the ideas of the constructions in [LPJY14] seem quite different.

Third, our NIZK in Section 7.1 is similar to the one by Jutla and Roy in [JR14] for DDH. However, in our opinion, our construction seems to be more modular and simpler to understand. In addition, under  $\kappa$ -Lin, with  $\kappa \geq 2$ , our construction is slightly more efficient in terms of CRS size and verification time.

### 7.4 Application: Threshold Cramer-Shoup-like Encryption Scheme (Variant)

In the construction of Section 5.5, we can replace the previous one-time simulation-sound NIZK by this new NIZK. This yields a threshold encryption where the ciphertext size only consists of 4 group elements as the original Cramer-Shoup encryption scheme, at the expense of having a public key size linear in the security parameter.

Our two schemes are threshold and *structure-preserving* [AFG<sup>+</sup>10]: they are “compatible” with Groth-Sahai NIZK, in the sense that we can do a Groth-Sahai NIZK to prove that we know the plaintext of a ciphertext for our encryption schemes. In addition, normal decryption does not require any pairings, which still are very costly, compared to exponentiations. A detailed comparison with existing efficient IND-CCA encryption schemes based on cyclic or bilinear groups is given in Appendix D.1. To summarize, to the best of our knowledge, our two constructions are the most efficient threshold and structure-preserving IND-CCA encryption schemes.

**Table 1.** Comparison of NIZK for linear subspaces

	DDH (in $\mathbb{G}_2$ )			DLin (in $\mathbb{G}_1 = \mathbb{G}_2 = \mathbb{G}$ )			
	WS	Proof $ \pi $	CRS $ \sigma $	Pairings	Proof $ \pi $	CRS $ \sigma $	Pairings
[GS08]		$n + 2k$	5	$2n(k + 2)$	$2n + 3k$	6	$3n(k + 3)$
[JR13]	✓	$n - k$	$2k(n - k) + 2$	$(n - k)(k + 2)$	$2n - 2k$	$4k(n - k) + 3$	$2(n - k)(k + 2)$
[LPJY14]					3	$2n + 3k + 3$	$2n + 4$
[LPJY14] RSS					4	$4n + 8t + 5$	$2n + 6$
[LPJY14] USS					20	$2n + 3t + 3\nu + 10$	$2n + 30$
[JR14]	✓	1	$n + k + 1$	$n + 1$	2	$2(n + k + 2)$	$2(n + 2)$
§5.1		2	$n + 2k + 1$	$n + 2$	3	$2n + 3k + 2$	$2n + 3$
§7.1	✓	1	$n + k + 1$	$n + 1$	2	$2n + 2k + 2$	$2n + 2$
§5.3	OTSS	2	$2(n + 2k) + 1$	$2n + 2$	3	$2(2n + 3k) + 2$	$4n + 3$
§7.2	OTSS	✓	$2\nu(2n + 3k) + 2$	$\nu n + 2$	2	$2\nu(2n + 3k) + 2$	$2\nu n + 2$

- $n = n_1$ ,  $k = k_1$ , and  $\nu = 2\mathfrak{R}$ ; pairings: number of pairings required to verify the proof;
- sizes  $|\cdot|$  are measured in term of group elements ( $\mathbb{G}_1$  and  $\mathbb{G}_2$ , or  $\mathbb{G}$  if the bilinear group is symmetric). Generators  $g_1 \in \mathbb{G}_1$  and  $g_2 \in \mathbb{G}_2$  (for DDH in  $\mathbb{G}_2$ ) or  $g \in \mathbb{G}$  (for DLin) are not counted in the CRS;
- OTSS: one-time simulation-soundness; RSS: single-theorem relative simulation-soundness [JR12] (weaker than OTSS); USS: universal simulation-soundness (stronger than OTSS);
- WS: witness-samplability in [JR13], generation of  $\text{crs}$  so that  $\mathcal{T}_{\text{crs}_1}$  enables us to compute the discrete logarithms of  $\Gamma_1$ . This slightly restricts the set of languages which can be handled.

**Acknowledgments.** We would like to thank Jens Groth and the anonymous reviewers for detailed comments on a previous version of this paper. We also thank Victor Shoup for pointing out to us that the main idea of our generic framework was already present in the full version of [CS02]. ## A Formal Definitions

### A.1 Distances, Advantage and Success

**Statistical Distance.** Let  $\mathcal{D}_0$  and  $\mathcal{D}_1$  be two probability distributions over a finite set  $\mathcal{S}$  and let  $X_0$  and  $X_1$  be two random variables with these two respective distributions. The statistical distance between  $\mathcal{D}_0$  and  $\mathcal{D}_1$  is also the statistical distance between  $X_0$  and  $X_1$ :

$$\text{Dist}(\mathcal{D}_0, \mathcal{D}_1) = \text{Dist}(X_0, X_1) = \sum_{x \in \mathcal{S}} |\Pr[X_0 = x] - \Pr[X_1 = x]|.$$

If the statistical distance between  $\mathcal{D}_0$  and  $\mathcal{D}_1$  is less than or equal to  $\varepsilon$ , we say that  $\mathcal{D}_0$  and  $\mathcal{D}_1$  are  $\varepsilon$ -close or are  $\varepsilon$ -statistically indistinguishable. If the  $\mathcal{D}_0$  and  $\mathcal{D}_1$  are 0-close, we say that  $\mathcal{D}_0$  and  $\mathcal{D}_1$  are perfectly indistinguishable.

**Success/Advantage.** When one considers an experiment  $\text{Exp}^{\text{sec}}(\mathcal{A}, \mathfrak{K})$  in which adversary  $\mathcal{A}$  plays a security game SEC, we denote  $\text{Succ}^{\text{sec}}(\mathcal{A}, \mathfrak{K}) = \Pr[\text{Exp}^{\text{sec}}(\mathcal{A}, \mathfrak{K}) = 1]$  the success probability of this adversary. We additionally denote  $\text{Succ}^{\text{sec}}(t, \mathfrak{K}) = \max_{\mathcal{A} \leq t} \{\text{Succ}^{\text{sec}}(\mathcal{A}, \mathfrak{K})\}$ , the maximal success any adversary running within time  $t$  can get. As in the whole paper, the time-complexity  $t$  of an experiment should include the maximum execution time of the experiment plus the size of the code for the adversary, all in some fixed RAM model.

When one considers a pair of experiments  $\text{Exp}^{\text{sec}-b}(\mathcal{A}, \mathfrak{K})$ , for  $b = 0, 1$ , in which adversary  $\mathcal{A}$  plays a security game SEC, we denote

$$\text{Adv}^{\text{sec}}(\mathcal{A}, \mathfrak{K}) = \Pr[\text{Exp}_{\mathcal{A}}^{\text{sec}-0}(\mathfrak{K}) = 1] - \Pr[\text{Exp}_{\mathcal{A}}^{\text{sec}-1}(\mathfrak{K}) = 1],$$

the advantage of this adversary. We additionally denote  $\text{Adv}^{\text{sec}}(t, \mathfrak{K}) = \max_{\mathcal{A} \leq t} \{\text{Adv}^{\text{sec}}(\mathcal{A}, \mathfrak{K})\}$ , the maximal advantage any adversary running within time  $t$  can get. In an equivalent way, we can consider the experiment  $\text{Exp}^{\text{sec}}(\mathcal{A}, \mathfrak{K})$  where we first choose a random bit  $b$  and then run experiment  $\text{Exp}^{\text{sec}-b}(\mathcal{A}, \mathfrak{K})$ . Then the advantage is

$$\text{Adv}^{\text{sec}}(\mathcal{A}, \mathfrak{K}) = 2 \cdot \Pr[\text{Exp}^{\text{sec}}(\mathcal{A}, \mathfrak{K}) = b] - 1.$$

### A.2 Formal Definition of the Primitives

**Hash Function Family.** A hash function family  $(\mathcal{HF}_{\mathfrak{K}})_{\mathfrak{K}}$  is an ensemble (indexed by  $\mathfrak{K}$ , the security parameter) of families of functions  $\mathcal{H}$  from  $\{0, 1\}^*$  to a fixed-length output, either  $\{0, 1\}^k$  or  $\mathbb{Z}_p$ . Such a family is said *collision-resistant* if any polynomial-time adversary  $\mathcal{A}$  on a random function  $\mathcal{H} \xleftarrow{\$} \mathcal{HF}$  cannot find a collision with non-negligible probability (on  $\mathfrak{K}$ ). More precisely, we denote

$$\text{Succ}^{\text{coll}}(\mathcal{A}, \mathfrak{K}) = \Pr[\mathcal{H} \xleftarrow{\$} \mathcal{HF}_{\mathfrak{K}}, (m_0, m_1) \leftarrow \mathcal{A}(\mathcal{H}) : \mathcal{H}(m_0) = \mathcal{H}(m_1)].$$

**Labeled Encryption Scheme.** A labeled public-key encryption scheme  $\mathcal{E}$  is defined by four algorithms:

- $\text{SetupE}(1^{\mathfrak{K}})$ , where  $\mathfrak{K}$  is the security parameter, generates the global parameters  $\text{param}$  of the scheme;
- $\text{KGE}(\text{param})$  generates a pair of keys, the encryption key  $\text{ek}$  and the decryption key  $\text{dk}$ ;
- $\text{Encrypt}(\ell, \text{ek}, m; r)$  produces a ciphertext  $C$  on the input message  $m$  under the label  $\ell$  and encryption key  $\text{ek}$ , using the random coins  $r$ ;
- $\text{Decrypt}(\ell, \text{dk}, C)$  outputs the plaintext  $m$  encrypted in  $C$  under the label  $\ell$ , or  $\perp$ .

The first algorithm is often forgotten, to simplify notations. An encryption scheme  $\mathcal{E}$  should satisfy the following properties

- *Correctness*: for all key pairs  $(ek, dk)$ , all labels  $\ell$ , all random coins  $r$  and all messages  $m$ ,

$$\text{Decrypt}(\ell, dk, \text{Encrypt}(\ell, ek, m; r)) = m.$$

- *Indistinguishability under chosen-ciphertext attacks*: this security notion (IND-CCA) can be formalized by the security game in Fig. 5, where the adversary  $\mathcal{A}$  keeps some internal state between the various calls FIND and GUESS, and makes use of the oracle ODecrypt:
  - ODecrypt( $\ell, C$ ): This oracle outputs the decryption of  $C$  under the label  $\ell$  and the challenge decryption key  $dk$ . The input queries  $(\ell, C)$  are added to the list CTXT.

```

Exp $_{\mathcal{E}}^{\text{ind-cca-}b}(\mathcal{A}, \mathfrak{R})$ 
param  $\leftarrow$  SetupE( $1^{\mathfrak{R}}$ )
(ek, dk)  $\leftarrow$  KGE(param)
( $\ell^*, m_0, m_1$ )  $\leftarrow$   $\mathcal{A}$ (FIND : ek, ODecrypt( $\cdot, \cdot$ ))
 $C^* \leftarrow$  Encrypt( $\ell^*, ek, m_b$ )
 $b' \leftarrow$   $\mathcal{A}$ (GUESS :  $C^*$ , ODecrypt( $\cdot, \cdot$ ))
if ( $\ell^*, C^*$ )  $\in$  CTXT then return 0
else return  $b'$ 

```

Fig. 5. Experiments  $\text{Exp}_{\mathcal{E}}^{\text{ind-cca-}n}$  for the IND-CCA security

The advantages are

$$\begin{aligned} \text{Adv}_{\mathcal{E}}^{\text{ind-cca}}(\mathcal{A}) &= \Pr[\text{Exp}_{\mathcal{E}}^{\text{ind-cca-}1}(\mathcal{A}, \mathfrak{R}) = 1] - \Pr[\text{Exp}_{\mathcal{E}}^{\text{ind-cca-}0}(\mathcal{A}, \mathfrak{R}) = 1] \\ \text{Adv}_{\mathcal{E}}^{\text{ind-cca}}(t, q_d) &= \max_{\mathcal{A} \leq t, q_d} \{\text{Adv}_{\mathcal{E}}^{\text{ind-cca}}(\mathcal{A})\}, \end{aligned}$$

where we bound the adversaries to work within time  $t$  and to ask at most  $q_d$  decryption queries.

In some cases, *indistinguishability under chosen-plaintext attacks* (IND-CPA) is enough. This notion is similar to the above IND-CCA except that the adversary has no decryption-oracle ODecrypt access:

$$\begin{aligned} \text{Adv}_{\mathcal{E}}^{\text{ind-cpa}}(\mathcal{A}) &= \Pr[\text{Exp}_{\mathcal{E}}^{\text{ind-cpa-}1}(\mathcal{A}, \mathfrak{R}) = 1] - \Pr[\text{Exp}_{\mathcal{E}}^{\text{ind-cpa-}0}(\mathcal{A}, \mathfrak{R}) = 1] \\ \text{Adv}_{\mathcal{E}}^{\text{ind-cpa}}(t) &= \max_{\mathcal{A} \leq t} \{\text{Adv}_{\mathcal{E}}^{\text{ind-cpa}}(\mathcal{A})\}, \end{aligned}$$

where we bound the adversaries to work within time  $t$ :  $\text{Adv}_{\mathcal{E}}^{\text{ind-cpa}}(t) = \text{Adv}_{\mathcal{E}}^{\text{ind-cca}}(t, 0)$ .

### A.3 Concrete Instantiations

**IND-CPA Encryption: ElGamal.** The ElGamal encryption scheme [ELG84] is defined as follows:

- SetupE( $1^{\mathfrak{R}}$ ) generates a group  $\mathbb{G}$  of order  $p$ , with a generator  $g$ ;
- KGE(param) generates  $dk = z \xleftarrow{\$} \mathbb{Z}_p$ , and sets,  $ek = h = g^z$ ;
- Encrypt( $ek, M; r$ ), for a message  $M \in \mathbb{G}$  and a random scalar  $r \in \mathbb{Z}_p$ , the ciphertext is  $C = (u = g^r, v = M \cdot h^r)$ ;
- Decrypt( $dk, C$ ): one computes  $M = v/u^z$  and outputs  $M$ .

This scheme is indistinguishable against chosen-plaintext attacks (IND-CPA), under the DDH assumption.

**IND-CCA Encryption: Cramer-Shoup (CS).** The Cramer-Shoup encryption scheme (proposed in [CS98]) can be turned into a labeled public-key encryption scheme:

- $\text{SetupE}(1^{\mathfrak{R}})$  generates a group  $\mathbb{G}$  of order  $p$ , with a generator  $g$ ;
- $\text{KGE}(\text{param})$  generates  $(g_1, g_2) \xleftarrow{\$} \mathbb{G}^2$ ,  $\text{dk} = (x_1, x_2, y_1, y_2, z) \xleftarrow{\$} \mathbb{Z}_p^5$ , and sets,  $C = g_1^{x_1} g_2^{x_2}$ ,  $d = g_1^{y_1} g_2^{y_2}$ , and  $h = g_1^z$ . It also chooses a collision-resistant hash function  $\mathcal{H}$  in a hash family  $\mathcal{HF}$  (or simply a Universal One-Way Hash Function). The encryption key is  $\text{ek} = (g_1, g_2, c, d, h, \mathcal{H})$ ;
- $\text{Encrypt}(\ell, \text{ek}, M; r)$ , for a message  $M \in \mathbb{G}$  and a random scalar  $r \in \mathbb{Z}_p$ , the ciphertext is  $C = (\ell, u_1 = g_1^r, u_2 = g_2^r, v = M \cdot h^r, w = (cd^\xi)^r)$ , where  $v$  is computed after  $\xi = \mathcal{H}((\ell, u_1, u_2, v))$ .
- $\text{Decrypt}(\ell, \text{dk}, C)$ : one first computes  $\xi = \mathcal{H}((\ell, u_1, u_2, v))$  and checks whether  $u_1^{x_1 + \xi y_1} \cdot u_2^{x_2 + \xi y_2} \stackrel{?}{=} v$ . If the equality holds, one computes  $M = v/u_1^z$  and outputs  $M$ . Otherwise, one outputs  $\perp$ .

This scheme is indistinguishable against chosen-ciphertext attacks (IND-CCA), under the DDH assumption and if one uses a collision-resistant hash function  $\mathcal{H}$ .

**IND-CCA Encryption under DLin: Linear Cramer-Shoup.** The Linear Cramer-Shoup encryption scheme [Sha07] is a variant of Cramer-Shoup IND-CCA under DLin, instead of DDH. So this scheme can be used with symmetric pairings. Here is the scheme:

- $\text{SetupE}(1^k)$  generates a group  $\mathbb{G}$  of order  $p$ , with three independent generators  $(g_1, g_2, g_3) \xleftarrow{\$} \mathbb{G}^3$ ;
- $\text{KGE}(\text{param})$  generates  $\text{dk} = (x_1, x_2, x_3, y_1, y_2, y_3, z_1, z_2, z_3) \xleftarrow{\$} \mathbb{Z}_p^9$ , and sets, for  $i = 1, 2$ ,  $c_i = g_i^{x_i} g_3^{x_3}$ ,  $d_i = g_i^{y_i} g_3^{y_3}$ , and  $h_i = g_i^{z_i} g_3^{z_3}$ . It also chooses a hash function  $\mathcal{H}$  in a collision-resistant hash family  $\mathcal{HF}$  (or simply a Universal One-Way Hash Function). The encryption key is  $\text{ek} = (c_1, c_2, d_1, d_2, h_1, h_2, \mathcal{H})$ .
- $\text{Encrypt}(\ell, \text{ek}, M; r, s)$ , for a message  $M \in \mathbb{G}$  and two random scalars  $r, s \xleftarrow{\$} \mathbb{Z}_p$ , the ciphertext is  $C = (u_1 = g_1^r, u_2 = g_2^s, u_3 = g_3^{r+s}, v = M \cdot h_1^r h_2^s, w = (c_1 d_1^\xi)^r (c_2 d_2^\xi)^s)$ , where  $v$  is computed afterwards with  $\xi = \mathcal{H}((\ell, u_1, u_2, u_3, v))$ .
- $\text{Decrypt}(\ell, \text{dk}, C = (u_1, u_2, u_3, v, w))$ : one first computes  $\xi = \mathcal{H}((\ell, u_1, u_2, u_3, v))$  and checks whether  $u_1^{x_1 + \xi y_1} \cdot u_2^{x_2 + \xi y_2} \cdot u_3^{x_3 + \xi y_3} \stackrel{?}{=} v$ . If the equality holds, one computes  $M = v / (u_1^{z_1} u_2^{z_2} u_3^{z_3})$  and outputs  $M$ . Otherwise, one outputs  $\perp$ .

This scheme is indistinguishable against chosen-ciphertext attacks, under the DLin assumption and if one uses a collision-resistant hash function  $\mathcal{H}$ .

#### A.4 Smooth Projective Hash Functions and Hard Subset Membership Problems

In Section 3.2, we define the notion of perfect smoothness or 0-smoothness. This can be generalized to the notion of (statistical)  $\varepsilon$ -smoothness as follows. An SPHF is  $\varepsilon$ -smooth if for any  $\text{crs}$ , and any function (not necessarily computable in polynomial time)  $f$  from the set of projection keys to  $\mathcal{X}_{\text{crs}}$ , so that  $C = f(\text{hp})$  is such that  $C \notin \mathcal{L}_{\text{crs}}$ , the two following distributions are  $\varepsilon$ -statistically close:

$$\left\{ (\text{hp}, H) \left| \begin{array}{ll} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); & \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ C \leftarrow f(\text{hp}); & H \leftarrow \text{Hash}(\text{hk}, \text{crs}, C) \end{array} \right. \right\}$$

$$\left\{ (\text{hp}, H) \left| \begin{array}{ll} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); & \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ C \leftarrow f(\text{hp}); & H \xleftarrow{\$} \Pi \end{array} \right. \right\}.$$

An SPHF is smooth if it is  $\varepsilon$ -smooth with  $\varepsilon$  negligible (in the security parameter  $\mathfrak{R}$ ). When  $\varepsilon = 0$ , this definition is equivalent to the definition in Section 3.2, because, when the two distributions are identical, the fact that  $C$  can depend on  $\text{hp}$  gives no advantage to the adversary.

```

Expsubset-memb-b( $\mathcal{A}, \mathfrak{R}$ )
  ( $\text{crs}, \mathcal{T}_{\text{crs}}$ )  $\stackrel{\$}{\leftarrow}$  Setupcrs( $1^{\mathfrak{R}}$ );
  if  $b = 0$  then  $C \stackrel{\$}{\leftarrow} \mathcal{L}_{\text{crs}}$ 
  else  $C \stackrel{\$}{\leftarrow} \mathcal{X}_{\text{crs}} \setminus \mathcal{L}_{\text{crs}}$ 
  return  $\mathcal{A}(\text{crs}, C)$ 

```

### A.5 (Quasi-Adaptive) Non-Interactive Zero-Knowledge Proofs

Let us first recall some definitions from [Gro06, JR13], extended to the case of labeled non-interactive proof systems. We consider the quasi-adaptive setting of Jutla and Roy [JR13], where the common reference string (CRS) may depend on the language considered. In addition, the soundness property is only computational, so our NIZK is actually an argument and not a proof. However, this setting, though slightly weaker than usual settings, is sufficient for most cases.

**Non-Interactive Proof System.** Intuitively a proof system is a protocol which enables a prover to prove to a verifier that a given word or statement  $x$  is in a given NP-language. We are interested in non-interactive proofs, i.e., proofs such that the prover just sends one message.

More formally, as for SPHF, let  $\mathcal{L}_{\text{crs}}$  be a family of NP languages with witness relation  $\mathcal{R}_{\text{crs}}$ , i.e.,  $\mathcal{L}_{\text{crs}} = \{x \mid \exists w, \mathcal{R}_{\text{crs}}(x, w) = 1\}$ . The CRS  $\sigma$  for the NIZK (denoted by  $\psi$  in [JR13]) may depend on  $\text{crs}$  (denoted by  $\rho$  in [JR13]). We suppose that  $\text{crs}$  is generated by an algorithm  $\text{Setup}_{\text{crs}}$  (which may or may not also generate a trapdoor  $\mathcal{T}_{\text{crs}}$  associated to  $\text{crs}$ , see Section 3.2). The trapdoor  $\mathcal{T}_{\text{crs}}$  is only here to formalize properties like witness-samplability [JR13], and is only used in proofs. A labeled non-interactive proof system for  $(\mathcal{L}_{\text{crs}})$  is defined by a tuple  $\Pi = (\text{Setup}, \text{Prove}, \text{Ver}, \mathcal{L})$ , such that:

- $\mathcal{L}$  is a set of labels. For a classical non-interactive proof system,  $\mathcal{L} = \{\perp\}$  (and in this case, the labels can be forgotten) and for a labeled one,  $\mathcal{L} = \{0, 1\}^*$ ;
- **Setup** is a probabilistic polynomial time algorithm which takes as input  $\text{crs}$  and outputs a common reference string (CRS)  $\sigma$ ;  $\text{crs}$  is implicitly supposed to be contained in  $\sigma$ ;
- **Prove** is a probabilistic polynomial time algorithm which takes as input a CRS  $\sigma \stackrel{\$}{\leftarrow} \text{Setup}(\text{crs})$ ,  $\text{crs}$ , a label  $\ell \in \mathcal{L}$ , a word  $x \in \mathcal{L}$  and a witness  $w$  for  $x$  (such that  $\mathcal{R}_{\text{crs}}(x, w) = 1$ ), and outputs a proof  $\pi$  that  $x$  is in  $\mathcal{L}$ , for label  $\ell$ ;
- **Ver** is a deterministic algorithm which takes as input the CRS  $\sigma$ ,  $\text{crs}$ , a label  $\ell \in \mathcal{L}$ , a word  $x$  and a proof  $\pi$  and outputs 1 to indicate acceptance and 0 otherwise;

and such that it verifies the two following properties:

- **Quasi-adaptive completeness.** A non-interactive proof is complete if a honest prover knowing a statement  $x \in \mathcal{L}_{\text{crs}}$  and a witness  $w$  for  $x$  can convince an honest verifier that  $x$  is in  $\mathcal{L}_{\text{crs}}$ , for any label. More formally,  $\Pi$  is said perfectly complete, if for any adversary<sup>11</sup>  $\mathcal{A}$ , we have

$$\Pr \left[ (\text{crs}, \mathcal{T}_{\text{crs}}) \stackrel{\$}{\leftarrow} \text{Setup}_{\text{crs}}(1^{\mathfrak{R}}); \sigma \stackrel{\$}{\leftarrow} \text{Setup}(\text{crs}); (\ell, x, w, \pi) \stackrel{\$}{\leftarrow} \mathcal{A}(\sigma); \right. \\ \left. \mathcal{R}(x, w) = 0 \text{ and } \text{Ver}(\sigma, \text{crs}, \ell, x, \text{Prove}(\sigma, \text{crs}, \ell, x, w)) = 1 \right] = 0;$$

- **Quasi-adaptive soundness.** A non-interactive proof is said to be sound, if no polynomial time adversary  $\mathcal{A}$  can prove a false statement with non-negligible probability. More formally,  $\Pi$  is  $(t, \varepsilon)$ -sound if for any adversary  $\mathcal{A}$  running in time at most  $t$ :

$$\Pr \left[ (\text{crs}, \mathcal{T}_{\text{crs}}) \stackrel{\$}{\leftarrow} \text{Setup}_{\text{crs}}(1^{\mathfrak{R}}); \sigma \stackrel{\$}{\leftarrow} \text{Setup}(\text{crs}); (\ell, x, \pi) \stackrel{\$}{\leftarrow} \mathcal{A}(\sigma); \right. \\ \left. \text{Ver}(\sigma, \text{crs}, \ell, x, \pi) = 1 \text{ and } x \notin \mathcal{L}_{\text{crs}} \right] \leq \varepsilon.$$

<sup>11</sup> Unlike [JR13], we use a statistical definition for completeness.

**Non-Interactive Zero-Knowledge Proof (NIZK).** An (unbounded) NIZK (non-interactive zero-knowledge proof) is a non-interactive proof system with two simulators  $\text{Sim}_1$  and  $\text{Sim}_2$ , which can simulate **Setup** and **Prove**, but such that  $\text{Sim}_2$  does not need any witness. More formally a NIZK is defined by a tuple  $\mathbf{\Pi} = (\text{Setup}, \text{Prove}, \text{Ver}, \text{Sim}_1, \text{Sim}_2)$  such that  $(\text{Setup}, \text{Prove}, \text{Ver})$  is a non-interactive proof system, and:

- $\text{Sim}_1$  is a probabilistic algorithm which takes as input  $\text{crs}$  and generates a CRS  $\sigma$  and a trapdoor  $\mathcal{T}$ , such that  $\text{Sim}_2$  can use  $\mathcal{T}$  to simulate proofs under  $\sigma$ ;
- $\text{Sim}_2$  is a probabilistic algorithm which takes as input the CRS  $\sigma$ , a corresponding trapdoor  $\mathcal{T}$ ,  $\text{crs}$ , a label  $\ell$ , a word  $x$  (not necessarily in  $\mathcal{L}$ ), and outputs a (fake or simulated) proof  $\pi$  for  $x$ ;

and such that it verifies the following property, for any  $\text{crs}$ :

- **Quasi-adaptive (unbounded) zero-knowledge** A NIZK is said (unbounded) zero-knowledge if simulated proofs are indistinguishable from real proofs. More formally,  $\mathbf{\Pi}$  is  $(t, \varepsilon)$ -unbounded-zero-knowledge if, for any adversary running in time at most  $t$ :

$$\left| \Pr \left[ (\text{crs}, \mathcal{T}_{\text{crs}}) \stackrel{\$}{\leftarrow} \text{Setup}_{\text{crs}}(1^{\mathbb{R}}); \sigma \stackrel{\$}{\leftarrow} \text{Setup}(\text{crs}); \mathcal{A}(\sigma)^{\text{Prove}(\sigma, \text{crs}, \cdot, \cdot)} = 1 \right] - \Pr \left[ (\text{crs}, \mathcal{T}_{\text{crs}}) \stackrel{\$}{\leftarrow} \text{Setup}_{\text{crs}}(1^{\mathbb{R}}); (\sigma, \mathcal{T}) \stackrel{\$}{\leftarrow} \text{Sim}_1(1^{\mathbb{R}}); \mathcal{A}(\sigma)^{\text{Sim}'(\sigma, \mathcal{T}, \text{crs}, \cdot, \cdot)} = 1 \right] \right| \leq \varepsilon$$

where  $\text{Sim}'(\sigma, \mathcal{T}, \text{crs}, \ell, x, w) = \text{Sim}_2(\sigma, \mathcal{T}, \text{crs}, \ell, x)$ , if  $\mathcal{R}_{\text{crs}}(x, w) = 1$ , and  $\perp$  otherwise.

We are also interested in the following additional property:

- **One-Time Simulation Soundness.** A NIZK is said to be one-time simulation-sound if the adversary cannot prove a false statement, even if he can see one simulated proof for a word  $x$  of its choice. More formally,  $\mathbf{\Pi}$  is  $(t, \varepsilon)$ -one-time-simulation-sound if, for any adversary running in time at most  $t$ :

$$\Pr \left[ (\text{crs}, \mathcal{T}_{\text{crs}}) \stackrel{\$}{\leftarrow} \text{Setup}_{\text{crs}}(1^{\mathbb{R}}); (\sigma, \mathcal{T}) \stackrel{\$}{\leftarrow} \text{Sim}_1(1^{\mathbb{R}}); (x, \ell, \pi) \stackrel{\$}{\leftarrow} \mathcal{A}^{\text{Sim}_2(\sigma, \mathcal{T}, \text{crs}, \cdot, \cdot)}(\sigma); \text{Ver}(\sigma, \ell, x, \pi) = 1, (\ell, x, \pi) \notin S \text{ and } x \notin \mathcal{L}_{\text{crs}} \right] \leq \varepsilon$$

where  $\text{Sim}_2$  can be queried at most one time, and  $S$  is the set of  $(\ell, x, \pi)$  queried to  $\text{Sim}_2$  (either  $S$  is empty or  $S$  contains the only query to  $\text{Sim}_2$ ).

## B Additional Details

### B.1 Graded Rings, Sub-Graded Rings, and Multiplicative Compatibility

Let us first recall the notion of graded ring introduced in [BBC<sup>+</sup>13]. Graded rings are a generalization of bilinear groups and can be used as a practical abstraction of multilinear maps coming from the framework of Garg, Gentry and Halevi [GGH13].

Although, in this article, we focus on bilinear groups, all we do can easily be extended to ideal multilinear groups. Unfortunately, as explained in Footnote 2, no current candidate multilinear map construction is known to work for our framework. Another advantage of using graded rings is that it also enables us to simplify notations.

**Indexes Set.** Let us consider a finite set of indexes  $\Lambda = \{0, \dots, \kappa\}^\tau \subset \mathbb{N}^\tau$ . In addition to considering the addition law  $+$  over  $\Lambda$ , we also consider  $\Lambda$  as a bounded lattice, with the two following laws:

$$\sup(\tilde{\mathbf{v}}, \tilde{\mathbf{v}}') = (\max(\tilde{\mathbf{v}}_1, \tilde{\mathbf{v}}'_1), \dots, \max(\tilde{\mathbf{v}}_\tau, \tilde{\mathbf{v}}'_\tau)) \quad \inf(\tilde{\mathbf{v}}, \tilde{\mathbf{v}}') = (\min(\tilde{\mathbf{v}}_1, \tilde{\mathbf{v}}'_1), \dots, \min(\tilde{\mathbf{v}}_\tau, \tilde{\mathbf{v}}'_\tau)).$$

We also write  $\tilde{v} < \tilde{v}'$  (resp.  $\tilde{v} \leq \tilde{v}'$ ) if and only if for all  $i \in \{1, \dots, \tau\}$ ,  $\tilde{v}_i < \tilde{v}'_i$  (resp.  $\tilde{v}_i \leq \tilde{v}'_i$ ). Let  $\bar{0} = (0, \dots, 0)$  and  $\top = (\kappa, \dots, \kappa)$ , be the minimal and maximal elements.

**Graded Ring.** The  $(\kappa, \tau)$ -graded ring over a commutative ring  $R$  is the set  $\mathfrak{G} = \Lambda \times R = \{[\tilde{v}, x] \mid \tilde{v} \in \Lambda, x \in R\}$ , where  $\Lambda = \{0, \dots, \kappa\}^\tau$ , with two binary operations  $(+, \bullet)$  defined as follows:

- for every  $u_1 = [\tilde{v}_1, x_1], u_2 = [\tilde{v}_2, x_2] \in \mathfrak{G}$ :  $u_1 + u_2 := [\sup(\tilde{v}_1, \tilde{v}_2), x_1 + x_2]$ ;
- for every  $u_1 = [\tilde{v}_1, x_1], u_2 = [\tilde{v}_2, x_2] \in \mathfrak{G}$ :  $u_1 \bullet u_2 := [\tilde{v}_1 + \tilde{v}_2, x_1 \cdot x_2]$  if  $\tilde{v}_1 + \tilde{v}_2 \in \Lambda$ , or  $\perp$  otherwise, where  $\perp$  means the operation is undefined and cannot be done.

We remark that  $\bullet$  is only a partial binary operation and we use the following convention:  $\perp + u = u + \perp = u \bullet \perp = \perp \bullet u = \perp$ , for any  $u \in \mathfrak{G} \cup \{\perp\}$ . Let  $\mathfrak{G}_{\tilde{v}}$  be the additive group  $\{u = [\tilde{v}', x] \in \mathfrak{G} \mid \tilde{v}' = \tilde{v}\}$  of graded ring elements of index  $\tilde{v}$ .

Both  $+$  and  $\bullet$  are associative and commutative, over  $\mathfrak{G} \cup \{\perp\}$ . More precisely, for any  $u_1, u_2, u_3 \in \mathfrak{G} \cup \{\perp\}$ :  $u_1 + (u_2 + u_3) = (u_1 + u_2) + u_3$ ,  $u_1 \bullet (u_2 \bullet u_3) = (u_1 \bullet u_2) \bullet u_3$ ,  $u_1 + u_2 = u_2 + u_1$ , and  $u_1 \bullet u_2 = u_2 \bullet u_1$ . In particular, if  $u_1 \bullet (u_2 \bullet u_3) \neq \perp$  (i.e., if this expression is well-defined), then  $(u_1 \bullet u_2) \bullet u_3 \neq \perp$ . In addition, the operation  $\bullet$  is distributive over  $+$ : for any  $u_1, u_2, u_3 \in \mathfrak{G} \cup \{\perp\}$ ,  $u_1 \bullet (u_2 + u_3) = u_1 \bullet u_2 + u_1 \bullet u_3$ .

Thanks to the previous properties, we can make natural use of vector and matrix operations over graded ring elements. In particular, we say that  $\mathfrak{G}^n$  and  $\mathfrak{G}^{1 \times n}$  are *vector spaces* over the graded ring  $\mathfrak{G}$ . The canonical basis  $(e_i)_{i=1}^n$  of  $\mathfrak{G}^{1 \times n}$  is defined as usual, except the vectors of the canonical basis are of index  $\bar{0}$  (i.e., can be considered as “scalars”). Finally, if  $F$  is a family of vectors,  $\langle F \rangle$  denotes the vector space generated by  $F$ .

**Sub-Graded Ring and Multiplicative Compatibility.** A sub-graded ring of a graded ring  $\mathfrak{G}$  is a subset  $\mathfrak{G}_{\leq \tilde{v}} = \{u = [\tilde{v}', x] \in \mathfrak{G} \mid \tilde{v}' \leq \tilde{v}\}$  of  $\mathfrak{G}$ . A sub-graded ring is itself a graded ring (or more precisely, is isomorphic to a graded ring). Two sub-graded ring  $\mathfrak{G}_1 = \mathfrak{G}_{\leq \tilde{v}_1}$  and  $\mathfrak{G}_2 = \mathfrak{G}_{\leq \tilde{v}_2}$  are said to be *multiplicatively compatible* if  $\tilde{v}_1 + \tilde{v}_2 \in \Lambda$ , or in other words, if it is possible to multiply any element in  $\mathfrak{G}_{\leq \tilde{v}_1}$  by an element in  $\mathfrak{G}_{\leq \tilde{v}_2}$ .

**Cyclic Groups, Asymmetric Bilinear Groups, and Notations.** Let us now show that cyclic groups and bilinear groups of order  $p$  can be seen as graded rings over  $R = \mathbb{Z}_p$ :

**Cyclic groups:**  $\kappa = \tau = 1$ . More precisely, elements  $[0, x]$  of index 0 correspond to scalars  $x \in \mathbb{Z}_p$  and elements  $[1, x]$  of index 1 correspond to group elements  $g^x \in \mathbb{G}$ .

**Asymmetric bilinear groups**  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$ :  $\kappa = 1$  and  $\tau = 2$ . More precisely, we can consider the following map:  $[(0, 0), x]$  corresponds to  $x \in \mathbb{Z}_p$ ,  $[(1, 0), x]$  corresponds to  $g_1^x \in \mathbb{G}_1$ ,  $[(0, 1), x]$  corresponds to  $g_2^x \in \mathbb{G}_2$  and  $[(1, 1), x]$  corresponds to  $e(g_1, g_2)^x \in \mathbb{G}_T$ .

The two non-trivial sub-graded rings of this bilinear group are  $\mathfrak{G}_{\leq (1,0)}$  and  $\mathfrak{G}_{\leq (0,1)}$ . These two sub-graded rings are multiplicatively compatible, since  $(1, 0) + (0, 1) = (1, 1)$ . By abuse of notation, we often call these sub-graded rings:  $\mathbb{G}_1$  and  $\mathbb{G}_2$ .

**Symmetric bilinear groups**  $(p, \mathbb{G}, \mathbb{G}_T, e, g)$ :  $\kappa = 2$  and  $\tau = 1$ . More precisely, we can consider the following map:  $[0, x]$  corresponds to  $x \in \mathbb{Z}_p$ ,  $[1, x]$  corresponds to  $g^x \in \mathbb{G}$ , and  $[2, x]$  corresponds to  $e(g, g)^x \in \mathbb{G}_T$ .

The non-trivial sub-graded ring of this bilinear group is  $\mathfrak{G}_{\leq 1}$ . This sub-graded ring is multiplicatively compatible with itself, since  $1 + 1 = 2 = \kappa$ . By abuse of notation, we often call this sub-graded ring:  $\mathbb{G}$ .

We have chosen an additive notation for the group law in  $\mathfrak{G}_{\tilde{v}}$ , due to the fact that it simplifies the description of our constructions in the generic framework. Unfortunately, this choice of notation also makes it is somewhat cumbersome when dealing with bilinear groups. Hence, when we provide an example with a bilinear group  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e)$ , we use multiplicative notation  $\cdot$  for the law in  $\mathbb{G}_1$ ,  $\mathbb{G}_2$  and  $\mathbb{G}_T$ , and additive notation  $+$  for the law in  $\mathbb{Z}_p$ , as soon as it is not too

complicated. Therefore, for any  $x, y \in \mathbb{Z}_p$ ,  $u_1, v_1 \in \mathbb{G}_1$ ,  $u_2, v_2 \in \mathbb{G}_2$  and  $u_T, v_T \in \mathbb{G}_T$ , we have:

$$\begin{array}{ll} x + y = x + y & x \bullet y = x \cdot y = xy \\ u_1 + v_1 = u_1 \cdot v_1 = u_1 v_1 & x \bullet u_1 = u_1^x \\ u_2 + v_2 = u_2 \cdot v_2 = u_2 v_2 & x \bullet u_1 = u_1^x \\ u_T + v_T = u_T \cdot v_T & x \bullet u_T = u_T^x \\ & u_1 \bullet u_2 = e(u_1, u_2) \end{array}$$

## B.2 Technical Conditions for Diverse Vector Spaces

Let us write  $\mathfrak{I}(u)$  and  $\mathfrak{L}(u)$ , the index and the discrete logarithm (respectively) of an element  $u \in \mathfrak{G}$ : if  $u = [\tilde{v}, x]$ ,  $\mathfrak{I}(u) = \tilde{v} \in \Lambda$  and  $\mathfrak{L}(u) = x \in \mathbb{Z}_p$ . These notations can be extended to vectors of elements in  $\mathfrak{G}$ .

In this appendix, we detail the technical condition on indexes of  $\theta(C)$  and  $\Gamma$  sketched in Section 4.1, to ensure that:

- the indexes of coordinates of  $\theta(C)$  are independent of  $C$ ;
- there exists  $\lambda \in \mathfrak{G}^k$  such that

$$\hat{C} := \theta(C) = \Gamma \bullet \lambda,$$

if and only if there exists  $\mu \in \mathbb{Z}_p^k$  such that

$$\mathfrak{L}(\hat{C}) = \mathfrak{L}(\theta(C)) = \mathfrak{L}(\Gamma) \cdot \mu.$$

The technical condition states that there exists a vector of indexes  $\tilde{v}_\theta = (\tilde{v}_{\theta,i})_{i=1}^k \in \Lambda^k$  so that:

- for any  $C \in \mathcal{X}$  and any  $i = 1, \dots, k$ ,  $\mathfrak{I}(\hat{C}_i) = \tilde{v}_{\theta,i}$ , with  $\hat{C} = \theta(C)$ ;
- for any  $i = 1, \dots, k$  and  $j = 1, \dots, n$ ,  $\mathfrak{I}(\Gamma_{i,j}) \leq \tilde{v}_{\theta,i}$ .

## B.3 Concrete Equations for Disjunction of SPHFs

If we write down all equations, we get:

$$\begin{aligned} \text{hk} &= \alpha \stackrel{\S}{\leftarrow} \mathbb{Z}_p^{1 \times n} \\ \text{hp} &= (\gamma_j)_j \text{ with } \gamma_j = \begin{cases} \sum_{l=1}^{n_1} \alpha_{(l-1)n_2+i_2} \bullet \Gamma_{i_1,l}^{(1)} & \text{when } j = (i_1 - 1)n_2 + i_2 \\ \sum_{l=1}^{n_2} \alpha_{(i_1-1)n_2+l} \bullet \Gamma_{i_2,l}^{(2)} & \text{when } j = k_1 n_2 + (i_1 - 1)k_2 + i_2 \end{cases} \\ H &= \sum_{i_1=1}^{n_1} \sum_{i_2=1}^{n_2} \alpha_{i_1 n_2 + i_2} \bullet \hat{C}_{1,i_1} \bullet \hat{C}_{1,i_2} \\ H' &= \begin{cases} \sum_{i_1=1}^{n_1} \sum_{i_2=1}^{n_2} \lambda_{1,i_1} \bullet \hat{C}_{2,i_2} \bullet \gamma_{(i_1-1)n_2+i_2} & \text{if } \Gamma^{(1)} \bullet \lambda_1 = \hat{C}_1 \\ \sum_{i_1=1}^{n_1} \sum_{i_2=1}^{n_2} \lambda_{2,i_2} \bullet \hat{C}_{1,i_1} \bullet \gamma_{k_1 n_2 + (i_1-1)k_2 + i_2} & \text{if } \Gamma^{(2)} \bullet \lambda_2 = \hat{C}_2. \end{cases} \end{aligned}$$

These equations are not required to understand the paper and are essentially here for the sake of completeness.

## B.4 2-Smoothness

For the sake of completeness, here is a definition of statistical 2-smoothness, which is a slight extension of the definition in Section 5.2 and which is still sufficient for our purpose.

A tag-SPHF is  $\varepsilon$ -2-smooth if for any  $\text{crs}$ , for all functions  $f'$  and  $f$  from the set of projection keys to  $\mathcal{X} \times \text{Tags}$ , so that  $(C', \text{tag}') = f'(\text{hp})$  and  $(C, \text{tag}) = f(\text{hp})$  are such that  $C \notin \mathcal{L}_{\text{crs}}$  and  $\text{tag}' \neq \text{tag}$ , the two following distributions are  $\varepsilon$ -statistically close:

$$\left\{ \begin{array}{l} (\text{hp}, H', H) \mid \begin{array}{l} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); \quad \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ (C', \text{tag}') \leftarrow f'(\text{hp}) \quad H' \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C', \text{tag}')); \\ (C, \text{tag}) \leftarrow f(\text{hp}); \quad H \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C, \text{tag})) \end{array} \right\} \\ \left\{ \begin{array}{l} (\text{hp}, H', H) \mid \begin{array}{l} \text{hk} \xleftarrow{\$} \text{HashKG}(\text{crs}); \quad \text{hp} \leftarrow \text{ProjKG}(\text{hk}, \text{crs}); \\ (C', \text{tag}') \leftarrow f'(\text{hp}); \quad H' \leftarrow \text{Hash}(\text{hk}, \text{crs}, (C', \text{tag}')); \\ (C, \text{tag}) \leftarrow f(\text{hp}); \quad H \xleftarrow{\$} \Pi \end{array} \right\}.$$

In practice the tag  $\text{tag}_C$  of a word  $C$  will often be its hash value from a collision-resistant hash function.

## B.5 One-Time Simulation-Sound NIZK

The basic idea for this construction compared to the one in Section 5.3 is to use the tag bit-by-bit. So we just need to guess which bit is different between  $\text{tag}_{C_1}$  and  $\text{tag}_{C'_1}$ . This idea is inspired from [CW13].

More precisely, we show how to transform  $\mathcal{V}_1$  into another diverse vector space  $\tilde{\mathcal{V}}_1$  such that the disjunction of  $\tilde{\mathcal{V}}_1$  and  $\mathcal{V}_2$  yields a one-time simulation-sound NIZK.

Let us suppose tags are binary strings of length  $\nu$ :  $\text{Tags} = \{0, 1\}^\nu$ .  $\text{tag}_i$  represents the bit  $i \in \{1, \dots, \nu\}$  of  $\text{tag} \in \text{Tags}$ . We transform the original diverse vector space  $\mathcal{V}_1$  for  $\mathcal{L}_1$  (not the 2-smooth one) into  $\tilde{\mathcal{V}}_1 = (\mathcal{X}_1, \mathcal{L}_1, \mathcal{R}_1, \mathfrak{G}_1, \tilde{n}_1, \tilde{k}_1, \Gamma^{(1)}, \tilde{\theta}_1)$  with:

$$\tilde{\Gamma} = \begin{pmatrix} \Gamma & 0 & \dots & 0 \\ 0 & \Gamma & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \Gamma \end{pmatrix} \in \mathbb{G}^{\tilde{n}_1 \times \tilde{k}_1} \quad \tilde{\theta}(C, \text{tag}) = \begin{pmatrix} (1 - \text{tag}_1) \bullet \hat{C} \\ \text{tag}_1 \bullet \hat{C} \\ \vdots \\ (1 - \text{tag}_\nu) \bullet \hat{C} \\ \text{tag}_\nu \bullet \hat{C} \end{pmatrix} \in \mathbb{Z}_p^{\tilde{k}_1} \quad \begin{array}{l} \tilde{n}_1 = 2\nu n_1 \\ \tilde{k}_1 = 2\nu k_1. \end{array}$$

Now, we can construct a one-time simulation NIZK exactly as the NIZK from disjunction of an SPHF and a PrPHF in Section 7.1, except that  $\mathcal{V}_1$  is replaced by  $\tilde{\mathcal{V}}_1$ . Completeness and perfect unbounded zero-knowledge are straightforward. Let us now prove that the one-time simulation soundness property.

We suppose that the adversary asks for a simulated proof  $\pi'$  for some word  $C'_1$  and some label  $\ell'$ , and we write  $\text{tag}' = \mathcal{H}((C'_1, \ell'))$ ; then the adversary submits a proof  $\pi$  for a word  $C'_1 \notin \mathcal{L}_1$  and some label  $\ell$ , and we write  $\text{tag} = \mathcal{H}((C_1, \ell))$ . Thanks to the collision resistance of  $\mathcal{H}$ , we can assume that  $\text{tag}' \neq \text{tag}$ .

We then remark that we can write any hashing key  $\tilde{\text{hk}}$  for the disjunction of  $\tilde{\mathcal{V}}_1$  and  $\mathcal{V}_2$  as the concatenation of  $2\nu$  hashing keys for the disjunction of  $\mathcal{V}_1$  and  $\mathcal{V}_2$ :  $\hat{\text{hk}}_1, \dots, \hat{\text{hk}}_{2\nu}$  and that the hash value of  $C$  for  $\text{tag}$  and  $\tilde{\text{hk}}$  is just the product of the hash values of  $C$  for all the  $\hat{\text{hk}}_{2i+\text{tag}_i-1}$ . Therefore, we guess an index  $i$  and a bit  $b$  such that  $\text{tag}_i = b$  but  $\text{tag}'_i = 1 - b$ . If this guess is wrong, we just abort the reduction. Our guess will be correct with probability at least  $1/(2\nu)$  which makes our reduction polynomial time. Finally, we just need to remark that the mixed pseudo-randomness ensures that the hash value  $H$  of  $C$  for  $\text{tag}$  under  $\hat{\text{hk}}_{2i+\text{tag}_i-1}$  looks random, since  $\hat{\text{hk}}_{2i+\text{tag}_i-1}$  is only used to compute  $H$  and nothing else: the simulated proof  $\pi'$  is the hash value of  $\hat{C}'_1 \otimes \text{Id}_{n_2}$  with  $\text{tag}'_i \neq b$ , so  $\hat{\text{hk}}_{2i+\text{tag}_i-1}$  is not used to compute it. This shows that  $H$  is uniformly random. We conclude as in the proof of one-time simulation soundness in Section 5.3.

## C Proof of Mixed-Randomness

We suppose that  $\mathcal{T}_{\text{CRS}_1}$  contains enough information to be able to compute the discrete logarithm of elements of  $\Gamma^{(1)}$ , denoted  $\mathfrak{L}(\Gamma^{(1)})$ .

Let  $m = n_1 - \dim \mathcal{L}_1$ . First, let us remark that using hybrid methods on pseudo-randomness of  $\mathcal{L}_2$ , we can prove that the two following distributions of the tuple  $U = (C_2, (\text{hp}_{2,j}, H_{2,j})_{j=1}^m)$  are computationally indistinguishable:

- normal distribution:  $C_2 \stackrel{\$}{\leftarrow} \mathcal{L}_2$  and for each  $j$ ,  $\text{hp}_{2,j}$  is a valid projection key  $\gamma^{(2,j)} = (\gamma_l^{(2,j)})_{l=1}^{k_2}$  corresponding to some hashing key  $\text{hk}_{2,j} = \alpha^{(2,j)} \in \mathbb{Z}_p^{1 \times n_2}$ , and  $H_{2,j}$  is the hash value of  $C_2$  under  $\text{hk}_{2,j}$ ;
- random distribution:  $C_2$ ,  $\text{hp}_{2,j}$  and  $\text{hk}_{2,j}$  are defined the same way, but the values  $H_{2,j}$  are picked independently and uniformly at random.

The whole proof consists in constructing a valid projection key  $\text{hp} = (\gamma_j)_{j=1}^{k_1 n_2 + k_2 n_1}$  and a hash value  $H$ , given  $(\text{hp}_{2,j}, H_{2,j})_{j=1}^m$ , so that, if the previous tuple  $U$  comes from the normal distribution,  $H$  is a valid hash value, while otherwise it is uniformly random.

Let  $\Delta \in \mathbb{Z}_p^{n_1 \times m}$  be a matrix such that the solutions of the linear equation  $\mathbf{X} \bullet \mathfrak{L}(\Gamma^{(1)}) = 0$  (with unknown  $\mathbf{X} \in \mathbb{Z}_p^{1 \times n_1}$ ) are exactly the vectors  $\delta \bullet \Delta$  for  $\delta \in \mathbb{Z}_p^m$ . In other words, the rows of  $\Delta$  form a basis of the left kernel of  $\mathfrak{L}(\Gamma^{(1)})$ .  $\Delta$  can be obtained by doing a Gaussian elimination over  $\mathfrak{L}(\Gamma^{(1)})$ .

We set the row vector  $\gamma'^{(2)} \in \mathfrak{G}_2^{1 \times m k_2}$  to be the concatenation of the row vectors  $\gamma^{(2,j)}$ , the row vector  $\alpha'^{(2)} \in \mathbb{Z}_p^{1 \times m n_2}$  to be the concatenation of  $\alpha^{(2,j)}$  (for  $j = 1, \dots, m$ ), and the row vector  $\mathbf{H}_2 \in \mathfrak{G}_2^{1 \times m}$  to be  $\mathbf{H}_2 = (H_{2,j})_{j=1}^m$ . We then have:

$$\gamma'^{(2)} = \alpha'^{(2)} \bullet (\text{Id}_m \otimes \Gamma^{(2)}), \quad (2)$$

and, if  $U$  is from the normal distribution:

$$\mathbf{H}_2 = \alpha''^{(2)} \bullet (\text{Id}_m \otimes \hat{\mathbf{C}}_2), \quad (3)$$

and otherwise it is random, and we can write it as:

$$\mathbf{H}_2 = \alpha''^{(2)} (\text{Id}_m \otimes \hat{\mathbf{C}}_2), \quad (4)$$

with  $\alpha''^{(2)}$  a random row vector in  $\mathbb{Z}_p^{1 \times m n_2}$  (independent of  $\alpha'^{(2)}$ ).

We then pick a random column vector  $\varepsilon \in \mathbb{Z}_p^{n_1 n_2}$ , and we set:

$$\gamma^{(1)} := \varepsilon \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) \quad (5)$$

$$\gamma^{(2)} := \gamma'^{(2)} \bullet (\Delta \otimes \text{Id}_{n_2}) + \varepsilon \bullet (\text{Id}_{n_1} \otimes \Gamma^{(2)}) \quad (6)$$

$$H := \mathbf{H}_2 \bullet \Delta \bullet \hat{\mathbf{C}}_1 + \varepsilon \bullet (\hat{\mathbf{C}}_1 \otimes \hat{\mathbf{C}}_2) \quad (7)$$

Let us now prove that  $\text{hp} := (\gamma^{(1)}, \gamma^{(2)})$  is a valid projection key for some random vector  $\alpha$ , and that  $H$  is the correct hash value of  $(C_1, C_2)$  if the tuple  $U$  is distributed normally, and a random value otherwise.

For that purpose, let us set:

$$\alpha := \alpha'^{(2)} \bullet (\Delta \otimes \text{Id}_{n_2}) + \varepsilon. \quad (8)$$

This vector is uniformly random due do  $\varepsilon$ . In addition, from Eq. (5), we get:

$$\alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) = \alpha'^{(2)} \bullet ((\Delta \bullet \Gamma^{(1)}) \otimes \text{Id}_{n_2}) + \varepsilon \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) = \gamma^{(1)},$$

since  $\Delta \bullet \Gamma^{(1)} = 0$  by definition of  $\Delta$ . So  $\gamma^{(1)}$  is the correct first part of the projection key associated to  $\alpha$ . And, from Eqs. (2) and (6), we get:

$$\alpha \bullet (\text{Id}_{n_1} \otimes \Gamma^{(2)}) = \alpha'^{(2)} \bullet (\Delta \otimes \Gamma^{(2)}) + \varepsilon \bullet (\text{Id}_{n_1} \otimes \Gamma^{(2)}) = \gamma^{(2)},$$

because

$$\alpha'^{(2)} \bullet (\Delta \otimes \Gamma^{(2)}) = \alpha'^{(2)} \bullet (\text{Id}_m \otimes \Gamma^{(2)}) \bullet (\Delta \otimes \text{Id}_{n_2}) = \gamma'^{(2)} \bullet (\Delta \otimes \text{Id}_{n_2}),$$

so that  $\gamma^{(2)}$  is the correct second part of the projection key associated to  $\alpha$ , and  $\text{hp}$  is the projection key associated to  $\alpha$ .

– If  $U$  is from the normal distribution, Eqs. (3) and (7), we get:

$$\begin{aligned} H &= \alpha'^{(2)} \bullet (\text{Id}_m \otimes \hat{C}_2) \bullet \Delta \bullet \hat{C}_1 + \varepsilon \bullet (\hat{C}_1 \otimes \hat{C}_2) \\ &= \alpha'^{(2)} \bullet ((\Delta \bullet \hat{C}_1) \otimes \hat{C}_2) + \varepsilon \bullet (\hat{C}_1 \otimes \hat{C}_2) \\ &= \alpha'^{(2)} \bullet (\Delta \otimes \text{Id}_{n_2}) \bullet (\hat{C}_1 \otimes \hat{C}_2) + \varepsilon \bullet (\hat{C}_1 \otimes \hat{C}_2). \end{aligned}$$

and so by definition of  $\alpha$  (Eq. (8)), we have:

$$H = \alpha \bullet (\hat{C}_1 \otimes \hat{C}_2),$$

hence  $H$  is the hash value of  $(C_1, C_2)$  under the hashing key of  $\alpha$ . In this case, everything has been generated as in the mixed pseudo-randomness experiment  $\text{Exp}^{\text{mixed-ps-rnd-}b}$  (Fig. 4) for  $b = 0$ .

– if  $U$  is from the random distribution, as previously, from Eqs. (4) and (7), we get that:

$$H = \alpha' \bullet (\hat{C}_1 \otimes \hat{C}_2),$$

where

$$\alpha' = \alpha''^{(2)} \bullet \Delta + \varepsilon.$$

Since  $\alpha''^{(2)}$  is random and independent of everything else, and by definition of  $\Delta$ ,  $\alpha'$  can be seen as an independent hashing key chosen uniformly at random among the keys verifying:

$$\alpha' \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}) = \varepsilon \bullet (\Gamma^{(1)} \otimes \text{Id}_{n_2}).$$

Since  $C_1 \notin \mathcal{L}_1$ ,  $\hat{C}_1$  is linearly independent from rows of  $\Gamma^{(1)}$ , and  $\hat{C}_1 \otimes \hat{C}_2$  is linearly independent from rows of  $\Gamma^{(1)} \otimes \text{Id}_{n_2}$ , hence  $H = \alpha' \bullet (\hat{C}_1 \otimes \hat{C}_2)$  looks uniformly random. Therefore, in this case, where  $U$  is from the random distribution, everything has been generated as in the mixed pseudo-randomness experiment  $\text{Exp}^{\text{mixed-ps-rnd-}b}$  (Fig. 4) for  $b = 1$ .

Since the normal distribution of  $U$  is computationally indistinguishable from the random one, this proves the mixed pseudo-randomness property.

## D Application Details

### D.1 Threshold Cramer-Shoup-like Encryption Schemes

In this appendix, we give some details on our constructions of threshold Cramer-Shoup-like encryption schemes. We first give the non-threshold schemes together with an IND-CCA proof and then we show that these schemes can easily be decrypted in a threshold way.

**(Non-Threshold) Constructions.** Our two encryption schemes in Section 5.5 and Section 7.4 work as follows:

- $\text{SetupE}(1^k)$  generates an asymmetric bilinear group  $(p, \mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_T, e, g_1, g_2)$ ;
- $\text{KGE}(\text{param})$  generates  $\text{crs}_1 = (g_{1,1}, g_{1,2}) \xleftarrow{\$} (\mathbb{G}_1 \setminus \{1\})^2$  together with a CRS  $\sigma$  for a one-time simulation-sound NIZK for the language defined by the following witness relation:

$$\mathcal{R}_{1, \text{crs}_1}((u_1, u_2), r) = 1 \quad \text{if and only if} \quad u_1 = g_{1,1}^r \quad \text{and} \quad u_2 = g_{1,2}^r;$$

then it chooses  $z \xleftarrow{\$} \mathbb{Z}_p$  and sets  $h \leftarrow g_{1,1}^z$ . It also chooses a hash function  $\mathcal{H}$  in a collision-resistant hash family  $\mathcal{HF}$ . The encryption key is  $\text{ek} = (g_{1,1}, g_{1,2}, h, \sigma, \mathcal{H})$ , while the decryption key is  $\text{dk} = (z, \sigma, \mathcal{H})$ ;

- $\text{Encrypt}(\ell, \text{ek}, M; r)$ , for a message  $M \in \mathbb{G}$  and a random scalar  $r \in \mathbb{Z}_p$ , outputs the following ciphertext  $C = (\ell, u_1 = g_{1,1}^r, u_2 = g_{1,2}^r, v = M \cdot h^r, \pi = \text{Prove}(\sigma, (g_{1,1}, g_{1,2}), \xi, (u_1, u_2), r))$ , where  $\xi = \mathcal{H}((\ell, u_1, u_2, v))$ .
- $\text{Decrypt}(\ell, \text{dk}, C)$  first computes  $\xi = \mathcal{H}((\ell, u_1, u_2, v))$  and checks whether the proof  $\pi$  is valid ( $\text{Ver}(\sigma, (g_{1,1}, g_{1,2}), \xi, (u_1, u_2), \pi) \stackrel{?}{=} 1$ ). If the equality holds, it computes  $M = v/u_1^z$  and outputs  $M$ . Otherwise, it outputs  $\perp$ .

*First Construction.* Here is the concrete first construction of one-time simulation-sound NIZK, following the construction in Section 5.3:

- $\text{Setup}(\text{crs}_1)$  picks a random group element  $h_2 \in \mathbb{G}_2$  and a random vector  $\alpha \in \mathbb{Z}_p^8$  and sets:

$$\begin{aligned} \Gamma^{(1)} &:= \begin{pmatrix} g_{1,1} & 1 \\ g_{1,2} & 1 \\ 1 & g_{1,1} \\ 1 & g_{1,2} \end{pmatrix} \\ \Gamma^{(2)} &:= \begin{pmatrix} g_2 \\ h_2 \end{pmatrix} \\ \gamma^{(1)} &:= \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_2) = \alpha \bullet \begin{pmatrix} g_{1,1} & 1 & 1 & 1 \\ 1 & g_{1,1} & 1 & 1 \\ g_{1,2} & 1 & 1 & 1 \\ 1 & g_{1,2} & 1 & 1 \\ 1 & 1 & g_{1,1} & 1 \\ 1 & 1 & 1 & g_{1,1} \\ 1 & 1 & g_{1,2} & 1 \\ 1 & 1 & 1 & g_{1,2} \end{pmatrix} \\ \gamma^{(2)} &:= \alpha \bullet (\text{Id}_4 \otimes \Gamma^{(2)}) = \alpha \bullet \begin{pmatrix} g_2 & 1 & 1 & 1 \\ h_2 & 1 & 1 & 1 \\ 1 & g_2 & 1 & 1 \\ 1 & h_2 & 1 & 1 \\ 1 & 1 & g_2 & 1 \\ 1 & 1 & h_2 & 1 \\ 1 & 1 & 1 & g_2 \\ 1 & 1 & 1 & h_2 \end{pmatrix}; \end{aligned}$$

(where 1 is the group element  $1 \in \mathbb{G}_1$ ). The CRS is  $\sigma := (\gamma^{(1)}, \gamma^{(2)})$ , while the trapdoor is  $\mathcal{T} = \alpha$ .

- $\text{Prove}(\sigma, \text{crs}_1, \xi, (u_1, u_2), r)$  just sets  $\text{tag} = \xi$  and outputs the proof<sup>12</sup>

$$\pi \leftarrow \gamma^{(1)} \bullet \left( \begin{pmatrix} r \\ r\xi \end{pmatrix} \otimes \text{Id}_2 \right) = \gamma^{(1)} \bullet \begin{pmatrix} r & 0 \\ 0 & r \\ r\xi & 0 \\ 0 & r\xi \end{pmatrix}, \quad (9)$$

<sup>12</sup> In the original construction  $\text{tag}$  would be the hash value of  $\xi$  and  $(u_1, u_2)$  under some collision-resistant hash function, but here  $\xi$  already “contains”  $(u_1, u_2)$  so we can slightly simplify the construction by choosing  $\text{tag} = \xi$ .

which is a column vector of two elements in  $\mathbb{G}_1$ .

–  $\text{Ver}(\sigma, \text{crs}_1, \xi, (u_1, u_2), \pi)$  checks whether:

$$\pi \bullet \Gamma^{(2)} \stackrel{?}{=} \gamma^{(2)} \bullet \begin{pmatrix} u_1 \\ u_2 \\ u_1^\xi \\ u_2^\xi \end{pmatrix}. \quad (10)$$

If we know the trapdoor  $\mathcal{T}$  of the NIZK, namely the hashing key  $\alpha$  of the SPHF, the verification of the NIZK can be performed as follows:

$$\pi \stackrel{?}{=} \alpha \bullet \left( \begin{pmatrix} u_1 \\ u_2 \\ u_1^\xi \\ u_2^\xi \end{pmatrix} \otimes \text{Id}_2 \right) = \alpha \bullet \begin{pmatrix} u_1 & 1 \\ 1 & u_1 \\ u_2 & 1 \\ 1 & u_2 \\ u_1^\xi & 1 \\ 1 & u_1^\xi \\ u_2^\xi & 1 \\ 1 & u_2^\xi \end{pmatrix}. \quad (11)$$

Indeed, Eq. (11) is just Eq. (10) multiplied by the matrix  $\Gamma^{(2)}$ , so this verification method will always reject when the original one rejects, and the one-time simulation-soundness still holds. It just remains to check that using this stronger verification method does not break the completeness: the completeness still holds because Eq. (9) implies:

$$\begin{aligned} \pi &= \alpha \bullet (\Gamma^{(1)} \otimes \text{Id}_2) \bullet \left( \begin{pmatrix} r \\ r^\xi \end{pmatrix} \otimes \text{Id}_2 \right) = \alpha \bullet \left( \left( \Gamma^{(1)} \bullet \begin{pmatrix} r \\ r^\xi \end{pmatrix} \right) \otimes (\text{Id}_2 \bullet \text{Id}_2) \right) \\ &= \alpha \bullet \left( \begin{pmatrix} u_1 \\ u_2 \\ u_1^\xi \\ u_2^\xi \end{pmatrix} \otimes \text{Id}_2 \right). \end{aligned}$$

*Second Construction.* The second construction follows the construction in Section 7.2. It is very similar to the first one. The only difference is that the tag  $\text{tag} = \xi$  is used bit by bit, instead of all at once, and that the matrix  $\Gamma^{(1)}$  can be seen as a block diagonal matrix with  $\nu = |\xi|$  blocks equal to the above matrix  $\Gamma^{(1)}$ . Moreover, we remark that, as for the first construction, knowing the trapdoor  $\mathcal{T}$  of the NIZK enables us to decrypt without performing any pairing computations.

**IND-CCA Security Proof.** The proof is quite straightforward and basically uses ideas in the security proof of the Cramer-Shoup encryption scheme [CS98]. Here is a sketch of a sequence of games proving the IND-CCA property:

**Game  $\mathbf{G}_0$ :** This is the game for  $\text{Exp}_{\mathcal{E}}^{\text{ind-cca}-b}$  for  $b = 0$  (see Appendix A.2).

**Game  $\mathbf{G}_1$ :** In this game, we generate  $g_{1,2}$  as  $g_{1,1}^t$  (with  $t \stackrel{\$}{\leftarrow} \mathbb{Z}_p$ ) and reject all ciphertexts  $C = (u_1, u_2, v, \pi)$  submitted to the decryption oracle for which  $u_2 \neq u_1^t$ . This game is indistinguishable from the previous one under the soundness of the NIZK, which ensures that if the proof  $\pi$  is not rejected,  $(g_{1,1}, g_{1,2}, u_1, u_2)$  is a DDH tuple.

**Game  $\mathbf{G}_2$ :** In this game, we generate  $h$  as  $h = g_{1,1}^{z_1} g_{1,2}^{z_2}$  (with  $z_1, z_2 \stackrel{\$}{\leftarrow} \mathbb{Z}_p$ ) instead of  $h = g_{1,1}^z$ . In addition, we decrypt ciphertexts  $C = (u_1, u_2, v, \pi)$  by first rejecting if  $\pi$  is not a valid proof or  $u_2 \neq u_1^t$  (as before) and then outputting  $v/(u_1^{z_1} u_2^{z_2})$  (instead of  $v/u_1^z$ ). This game is perfectly indistinguishable from the previous one, because  $h$  can be written  $h = g_{1,1}^{z_1 + tz_2}$  and  $u_1^{z_1} u_2^{z_2} = u_1^{z_1 + tz_2}$ .

**Game  $G_3$ :** In this game, we do not check anymore that  $u_2 = u_1^t$  and we generate  $g_{1,2}$  directly as a random group element in  $\mathbb{G}_1$ . This game is indistinguishable from the previous one under the soundness of the NIZK.

**Game  $G_4$ :** In this game, for the challenge ciphertext  $C^* = (u_1^*, u_2^*, v^*, \pi^*)$ , we compute  $v^*$  as  $v^* = u_1^{*z_1} u_2^{*z_2}$ , instead of  $h^r$ , where  $u_1 = g_{1,1}^r$  and  $u_2 = g_{1,2}^r$ . This game is perfectly indistinguishable from the previous one.

**Game  $G_5$ :** In this game, we simulate the proof  $\pi^*$  in the challenge ciphertext  $C^* = (u_1^*, u_2^*, v^*, \pi^*)$ . This game is indistinguishable from the previous one under the zero-knowledge property of the NIZK. In addition, in this game, knowledge of  $r$  in  $C^*$  is no longer required.

**Game  $G_6$ :** In this game, we replace  $(u_1^*, u_2^*)$  which was a DDH tuple in basis  $(g_{1,1}, g_{1,2})$  by a random tuple. This game is indistinguishable from the previous one under the DDH assumption.

**Game  $G_7$ :** In this game, we again generate  $g_{1,2}$  as  $g_{1,1}^t$  (with  $t \xleftarrow{\$} \mathbb{Z}_p$ ) and reject all ciphertexts  $C = (u_1, u_2, v, \pi)$  submitted to the decryption oracle for which  $u_2 \neq u_1^t$ . This game is indistinguishable from the previous one under the one-time simulation-soundness of the NIZK.

**Game  $G_8$ :** As in Cramer-Shoup’s proof [CS98], it is easy to show that the only information (from an information theoretic point of view) the adversary sees of  $z_1$  and  $z_2$  except from  $C^*$  is  $z_1 + tz_2$ . So  $u_1^{*z_1} u_2^{*z_2}$  looks completely random to the adversary if  $(u_1, u_2)$  is not a DDH tuple in basis  $(g_{1,1}, g_{1,2})$  (which happens with probability  $1 - 1/p$ ). Therefore we can replace  $v^*$  by a random value, and this game is statistically indistinguishable from the previous one. Finally, we can redo all the previous games in the reverse order and see that  $\text{Exp}_{\mathcal{E}}^{\text{ind-cca}-b}$  with  $b = 0$  is indistinguishable from  $\text{Exp}_{\mathcal{E}}^{\text{ind-cca}-b}$  with  $b = 1$ .

**Threshold Version.** The validity of the ciphertext can be verified publicly, just knowing  $ek$  (or more precisely  $\sigma$ ), and not  $dk$ , and then after this test has been performed, we just need to compute  $v/u_1^z$ , to get the message. We often say in this case that the ciphertext is “publicly verifiable”, though it is not clear that a proper definition exists.

In any case, this property just means that to threshold decrypt the ciphertext, we just need to use Shamir’s threshold secret sharing over  $\mathbb{Z}_p$  [Sha79], exactly as in [SG02]. If in addition, we want to be able to verify decryption shares without random oracle, we can replace the Fiat-Shamir-based NIZK in [SG02] by one of ours in Section 5.1.

**Comparison with Existing Schemes.** A comparison with existing efficient IND-CCA encryption schemes based on cyclic or bilinear groups is given in Table 2, whose entries have been partially derived from similar tables in [BMW05, Kil06].

The two other efficient threshold and structure-preserving IND-CCA encryption schemes are those based on the Canetti-Halevi-Katz [CHK04] transform, the one of Boyen, Mei and Waters [BMW05] and the one of Kiltz [Kil06]. But for all except the one of Kiltz, the plaintext and one element of the ciphertext has to be in  $\mathbb{G}_T$ , which limits usage of Groth-Sahai NIZK. In addition, elements in  $\mathbb{G}_T$  have a much longer representation than elements in  $\mathbb{G}$ ,  $\mathbb{G}_1$  or  $\mathbb{G}_2$ . And, even though our second encryption scheme uses exactly the same number of group elements as Kiltz’s encryption scheme [Kil06], these groups elements are about 50% smaller in practice, since we use an asymmetric pairing while Kiltz’s scheme uses a symmetric one. So even our first construction is more efficient (regarding ciphertext size) than Kiltz’s construction.

## D.2 One-Round Group Password Authenticated Key Exchange

In this appendix, we give some details on our one-round group password authenticated key exchange (GPAKE). We first give our construction, then recall the formal model and finally prove the security of our protocol.

**Protocol.** We first describe the protocol for 3 players for the sake of simplicity. But, it can easily be extended to  $n$  players using  $(n - 1)$ -way symmetric multilinear maps. However, since

ver key: verification key of a signature scheme, sig: signature, com: commitment

<sup>a</sup> #pairing + [#multi, #regular, #fix]-exponentiation (+ #multiplication) (in  $\mathbb{G}$  or  $\mathbb{G}_1$ ), a multi-exponentiation being a computation of the form  $a_1^{b_1} \cdots a_k^{b_k}$ , where  $a_1, \dots, a_k \in \mathbb{G}$  and  $b_1, \dots, b_k \in \mathbb{Z}_p$ ; the number of multiplications is approximate and only written when it depends on  $\mathfrak{R}$ , since multiplications are way faster than pairings and exponentiations;

<sup>b</sup> Number of other elements required to make the KEM (previous column) scheme, a structure preserving encryption scheme; see text;

<sup>c</sup> support threshold decryption;

<sup>d</sup> depends on parameters for the signature/commitment/mac and if we use symmetric or asymmetric groups, but a small constant in any case;

<sup>e</sup>  $\mathbb{G}$  has to be a cyclic group from a symmetric bilinear group, and so element representation is often 50% bigger than for the other scheme where  $\mathbb{G}$  is either just a cyclic group, or can be the first group ( $\mathbb{G}_1$ ) of an asymmetric bilinear group;

<sup>f</sup> supposing  $\nu = 2\mathfrak{R}$ .

each player needs to send an exponential number of group elements in  $n$ , this protocol is limited to small number  $n$  of users. Notice that the only known group one-round (non authenticated) key exchange is the group Diffie-Hellman key exchange [BS03], which also require  $(n - 1)$ -way symmetric multilinear maps.

In our protocol, we suppose that users participating in our one-round GPAKE are identified as  $U_1$ ,  $U_2$  and  $U_3$ . Let  $(p, \mathbb{G}, \mathbb{G}_T, e, g)$  be a symmetric bilinear group. The common reference string  $\text{crs}$  contains an encryption key  $\text{ek}$  for the linear Cramer-Shoup encryption scheme. The linear Cramer-Shoup encryption scheme [Sha07] recalled in Appendix A.3 is a variant of the Cramer-Shoup encryption scheme secure under DLin. We cannot use the original Cramer-Shoup scheme because DDH does not hold in symmetric bilinear groups. Let  $\mathcal{L}_{\text{crs}}$  be the language of tuples  $((\text{pw}_1, \ell_1, C_1), (\text{pw}_2, \ell_2, C_2))$ , where  $C_1$  (with label  $\ell_1$ ) is a valid Cramer-Shoup ciphertext of  $\text{pw}_1$  or  $C_2$  (with label  $\ell_2$ ) is a valid linear Cramer-Shoup ciphertext of  $\text{pw}_2$ . This language is the disjunction of two identical languages  $\mathcal{L}_1 = \mathcal{L}_2$ , namely the language of tuples  $(\text{pw}, \ell, C)$  of valid linear Cramer-Shoup ciphertexts  $C$  (with label  $\ell$ ) of  $\text{pw}$ . A diverse vector space for  $\mathcal{L}_1$  is recalled later in this appendix.

Let us describe the protocol for  $U_1$  with password  $\text{pw}_1$  (the protocol is symmetric for the other users): user  $U_1$  first generates an hashing key  $\text{hk}_1$  and an associated projection key  $\text{hp}_1$  for a 2-smooth SPHF on  $\mathcal{L}$ . Such a 2-smooth SPHF can be created using the generic transformation of Section 5.2. Then, he generates  $C_1 \stackrel{\$}{\leftarrow} \text{Encrypt}(\ell, \text{ek}, \text{pw}_1; r_1, s_1)$ , with label  $\ell = (U_1, U_2, U_3, \text{hp}_1)$  and random scalars  $r_1, s_1 \stackrel{\$}{\leftarrow} \mathbb{Z}_p$ . Finally, he sends  $C_1, \text{hp}_1$  to  $U_2$  and  $U_3$ .

Then after receiving  $C_2, \text{hp}_2$  from  $U_2$  and  $C_3, \text{hp}_3$  from  $U_3$ ,  $U_1$  computes  $\text{sk}$  as the product ( $\cdot$  in  $\mathbb{G}_T$ ) of the three following values:

$$\begin{aligned} & \text{Hash}(\text{hk}_1, \text{crs}, ((\text{pw}_1, \ell_2, C_2), (\text{pw}_1, \ell_3, C_3))) \\ & \text{ProjHash}(\text{hp}_2, \text{crs}, ((\text{pw}_1, \ell_1, C_1), (\text{pw}_1, \ell_3, C_3)), (r_1, s_1)) \\ & \text{ProjHash}(\text{hp}_3, \text{crs}, ((\text{pw}_1, \ell_1, C_1), (\text{pw}_1, \ell_2, C_2)), (r_1, s_1)), \end{aligned}$$

where  $\ell_2 = (U_1, U_2, U_3, \text{hp}_2)$  and  $\ell_3 = (U_1, U_2, U_3, \text{hp}_3)$ . Concretely, each user sends a ciphertext with 5 group elements, and a projection key with  $2 \times 7 \times 4 = 56$  group elements, which adds up to 61 group elements sent per user.

As shown later, this protocol is secure under the DLin assumption in  $\mathbb{G}$ . The proof is a very delicate extension of the proof of the one-round PAKE of Katz and Vaikuntanathan in [KV11], and may be of independent interest.

Its extension to  $n$  users would require to use an  $n$ -linear variant of Cramer-Shoup and to use an  $(n - 1)$ -smooth SPHF. The proof would hold under  $n$ -Lin. However, the size of the projection keys and the gap in the security reduction grow exponentially in  $n$ , and so we are limited to small values of  $n$ , which needs to be logarithmic in the security parameter  $\kappa$ .

**Formal Model.** Let us recall the model of group password authenticated key exchange for  $n$  users in [ABCP06].

We denote by  $U_1, \dots, U_n$  the parties that can participate in the key exchange protocol  $P$ . Each of them may have several *instances* called oracles involved in distinct, possibly concurrent, executions of  $P$ . We denote  $U_i$  instances by  $\Pi_{U_i}^s$ . To simplify notations,  $s$  is supposed to be an integer between 1 and  $q_{\text{session}}$ , and for any  $s$ , instances  $(\Pi_{U_i}^s)_{i=1}^n$  are supposed to run the protocol together. Each  $s$  therefore corresponds to a session of the protocol, and is called a session id. The parties share a low-entropy secret  $\text{pw}^*$  which is uniformly drawn from a small dictionary Password of size  $N$ .

The key exchange algorithm  $P$  is an interactive protocol between the  $U_i$ 's that provides the instances with a session key  $\text{sk}$ . During the execution of this protocol, the adversary has the entire control of the network, and tries to break the privacy of the key.

As in [ABCP06], we use the Real-or-Random notion for the semantic security instead of the Find-then-Guess. This notion is strictly stronger in the password-based setting. And actually, since we focus on the semantic security only, we can assume that each time a player accepts a key, the latter is revealed to the adversary, either in a real way, or in a random one (according to a bit  $b$ ). Let us briefly review each query:

- **Send**( $U_i, s, U_j, m$ ): This query enables us to consider active attacks by having  $\mathcal{A}$  sending a message to the instance  $\Pi_{U_i}^s$  in the name of  $U_j$ . The adversary  $\mathcal{A}$  gets back the response  $\Pi_{U_i}^s$  generates in processing the message  $m$  according to the protocol  $P$ . A special query **Send**( $U_i, s, \text{Start}$ ) initializes the instance  $\Pi_{U_i}^s$  and the key exchange algorithm, and thus the adversary receives the initial flows sent out by the instance.
- **Test** <sup>$b$</sup> ( $U_i, s$ ): This query models the misuse of the session key by instance  $\Pi_{U_i}^s$  (*known-key attacks*). The query is only available to  $\mathcal{A}$  if the attacked instance actually “holds” a session key. It either releases the actual key to  $\mathcal{A}$ , if  $b = 1$  or a random one, if  $b = 0$ . The random keys must however be consistent between users in the same session. Therefore, a random key is simulated by the evaluation of a random function on the view a user has of the session: all the partners have the same view, they thus have the same random key (but independent of the actual view.)

*Remark 8.* Note that it has been shown [AFP05] that this query is indeed enough to model *known-key attacks* (where **Reveal** queries, which always answer with the real keys, are available), and makes the model even stronger. Even though their result has only been proven in the two-party and three-party scenarios, one should note that their proof can be easily extended to the group scenario.

As already noticed, the aim of the adversary is to break the privacy of the session key (a.k.a., semantic security). This security notion takes place in the context of executing  $P$  in the presence of the adversary  $\mathcal{A}$ . One first draws a password  $\text{pw}^*$  from  $\text{Password}$ , flips a coin  $b$ , provides coin tosses to  $\mathcal{A}$ , as well as access to the  $\text{Test}^b$  and  $\text{Send}$  oracles.

The goal of the adversary is to guess the bit  $b$  involved in the  $\text{Test}$  queries, by outputting this guess  $b'$ . We denote the **AKE advantage** as the probability that  $\mathcal{A}$  correctly guesses the value of  $b$ . More precisely we define  $\text{Adv}_{\mathcal{A}}^{\text{ake}}(\mathfrak{R}) = 2\Pr[b = b'] - 1$ . The protocol  $P$  is said to be  $(t, \epsilon)$ -AKE-secure if  $\mathcal{A}$ 's advantage is smaller than  $\epsilon$  for any adversary  $\mathcal{A}$  running with time  $t$ .

We will denote by  $q_{\text{active}}$  the number of messages the adversary produced by himself (thus without including those he has just forwarded). This number upper-bounds the number of on-line “tests” the adversary performs to guess the password. And we denote by  $q_{\text{session}}$  the total number of sessions the adversary has initiated:  $nq_{\text{session}}$ , where  $n$  is the size of the group, upper-bounds the total number of messages the adversary has sent in the protocol (including those he has built and those he has just forwarded).

The best we can expect with such a scheme is that the adversary erases no more than 1 password for each *session* in which he plays actively (since there exists attacks which achieve that in any password-based scheme). However, in our scheme, we can just prevent the adversary from erasing more than 1 password for each *player* that he tries to impersonate, which was also the case for the scheme in [ABCP06]. So we want to prove that  $\text{Adv}_{\mathcal{A}}^{\text{ake}}(\mathfrak{R})$  is bounded by  $q_{\text{active}}/N$  plus some negligible term in  $\mathfrak{R}$ .

Finally, we are interested in one-round protocol, meaning that each player sends exactly one flow and all flows can be sent simultaneously. Since the communication channel is not assumed to be reliable, the adversary is allowed to modify messages, to delete them, and to alter the order in which these messages are received.

**SPHF for Linear Cramer-Shoup Ciphertexts.** Our construction needs an SPHF for the language defined by the following witness relation:

$$\mathcal{R}_{\text{crs}}((\text{pw}, \ell, C), r) \quad \text{if and only if} \quad C = \text{Encrypt}(\ell, \text{ek}, \text{pw}; r)$$

where  $\text{Encrypt}$  is the encryption algorithm for Linear Cramer-Shoup,  $\text{ek}$  is an encryption key (stored in  $\text{crs}$ ).

Here is a diverse vector space for the above language (using notations in Appendix A.3 for  $\text{ek}$ ):

$$\hat{\mathcal{X}} = \mathbb{G}^7 \quad \Gamma = \begin{pmatrix} g_1 & 1 & 1 & 1 \\ 1 & g_1 & 1 & 1 \\ 1 & 1 & g_2 & 1 \\ 1 & 1 & 1 & g_2 \\ g_3 & 1 & g_3 & 1 \\ h_1 & 1 & h_2 & 1 \\ c_1 & d_1 & c_2 & d_2 \end{pmatrix} \quad \theta((\text{pw}, \ell, C)) = \begin{pmatrix} u_1 \\ u_1^\xi \\ u_2 \\ u_2^\xi \\ u_3 \\ v/\text{pw} \\ w \end{pmatrix}$$

with  $C = (u_1, u_2, u_3, v, w)$  and  $\xi = \mathcal{H}((\ell, u_1, u_2, u_3, v))$ . It is a straightforward extension of the one for Cramer-Shoup encryption scheme introduced in [BBC+13].

**Security Proof.** The security proof is a delicate extension of the proof for the one-round PAKE of Katz and Vaikuntanathan in [KV11]. It also works for our extension of the protocol for  $n$  players (and not only for our protocol for  $n = 3$  players), as long as  $n$  is logarithmic in  $\mathfrak{R}$ .

Although our proof is self-contained, we highly recommend the reader to get familiar with the work of Katz and Vaikunthanatan [KV11] before reading this proof. The following paragraphs explain the main difference between our proof and their proof.

*Main Difficulties in the Proof.* Basically, the main difficulty in the proof comes from the fact that we have to be able to prove that the hash values computed by the honest user look random if the adversary only generated ciphertexts not containing the valid password  $\text{pw}^*$ . In the case of a two-player PAKE, this was handled by the technical lemma in [KV11]. Its proof basically consisted in an hybrid over all pairs of honestly generated hashing/projection key  $(\text{hk}, \text{hp})$  and an honestly generated ciphertext  $C$ . The hash value of  $C$  under  $\text{hk}$  can be proven to look random under the pseudo-randomness of the SPHF, which comes from the hard subset membership property of the underlying language (which itself comes from the IND-CCA property of the encryption scheme). More precisely, we could just replace  $C$  by an encryption of a dummy password, and that would prove that the hash value of  $C$  under  $\text{hp}$  looks random to someone not knowing  $\text{hk}$ . This is possible thanks to the IND-CCA property and the fact we do not need to use the random coins of  $C$  in that part of the game: these random coins are indeed only used to compute the resulting secret keys, but either these secret keys were already random (if one of the user involved in the session yielding the secret key is corrupted by the adversary and did not use the valid password), or these secret keys can be computed directly using the hashing keys of honest users, without requiring to know the random coins of  $C$ . That is why the hash value of  $C$  under  $\text{hk}$  can be replaced by a random value, and then we can change back  $C$  to a valid ciphertext of  $\text{pw}^*$  (and continue the hybrid argument...).

Unfortunately, in our case, we cannot simply do that, since hash values are now over  $n - 1$  ciphertexts, and as soon as one ciphertext is a valid ciphertext of  $\text{pw}^*$ , the hash value could be derived from the projection key  $\text{hp}$  (at least information theoretically). That is why we need to do a much more delicate hybrid over all sets  $S$  of possible honest players, and turn all the ciphertexts of these players into ciphertexts of dummy values, assuming there is only one session for each set of players to simplify. However, that needs to be done in the correct order, otherwise, we may not be able to compute the secret keys of the other players by doing so! Basically, what we show is that if we enumerate the sets  $S$  by increasing size, everything works.

Another subtlety is that the classical smoothness is not enough, and we need to use the  $(n - 1)$ -smoothness property.

*Proof Details.* We can assume that there are two kinds of **Send**-queries:  $\text{Send}_0(U_i, s, \text{Start})$  and  $\text{Send}_1(U_i, s, U_j, m)$ .  $\text{Send}_0(U_i, s, \text{Start})$ -queries are queries where the adversary asks the instance  $\Pi_{U_i}^s$  to send its flow. It is answered by the flow  $U_i$  should send to all the  $U_j$  with  $j \neq i$ .  $\text{Send}_1(U_i, s, U_j, m)$ -queries are queries where the adversary sends the message  $m$  to the instance  $\Pi_{U_i}^s$ . It gives no answer back, but, it may define the session key, for possible later **Test**-queries, when  $\Pi_{U_i}^s$  received a flow from all the other users ( $U_k$  with  $k \neq i, j$ ).

We write  $\text{Adv}_I(\mathcal{A})$  the advantage of  $\mathcal{A}$  in Game  $\mathbf{G}_I$  and  $\text{negl}()$  means negligible in  $\mathfrak{K}$ .

**Game  $\mathbf{G}_0$ :** This game is the real attack game.

**Game  $\mathbf{G}_1$ :** We first modify the way one answers the **Send**<sub>1</sub>-queries, by using a decryption oracle, or alternatively knowing the decryption key. More precisely, when a message  $(\text{hp}, C)$  is sent, two cases can appear:

- it has been generated (altered) by the adversary, then one first decrypts the ciphertext to get the password  $\text{pw}$  used by the adversary. And, if it is correct ( $\text{pw} = \text{pw}^*$ ) —event **EventStop**— one declares that  $\mathcal{A}$  succeeds (saying that  $b' = b$ ) and terminates the game. Otherwise, we do nothing;
- it is a replay of a previous flow sent by the simulator, then, in particular, one knows the hashing keys, and one can compute the associated hash values using the hashing key.

The first case can only increase the advantage of the adversary in case **EventStop** happens (which probability is computed in  $\mathbf{G}_4$ ). The second change does not affect the way the key is computed, so finally:  $\text{Adv}_0(\mathcal{A}) \leq \text{Adv}_1(\mathcal{A}) + \text{negl}(\mathfrak{K})$ .

**Game  $\mathbf{G}_2$ :** We modify the way the secret keys are computed: each time two simulated instances have corresponding transcripts, the second instance which computes the secret key, does not

recompute it but uses the one already computed by the first instance. More precisely, when an instance  $\Pi_{U_i}^s$  has received a message  $(\text{hp}_j, C_j)$  from  $U_j$  and previously received messages  $(\text{hp}_k, C_k)$  from all the other users  $U_k$  with  $k \neq i, j$ , and if another instance  $\Pi_{U_l}^t$  received the same messages  $(\text{hp}_k, C_k)$  for  $k \neq l$ , and sent  $(\text{hp}_l, C_l)$ , then we set the secret key of  $\Pi_{U_i}^s$  to be the one computed by  $\Pi_{U_l}^t$ . This change is only formal and  $\text{Adv}_1(\mathcal{A}) = \text{Adv}_2(\mathcal{A})$ .

**Game  $\mathbf{G}_3$ :** We modify again the way one answers the  $\text{Send}_1$ -queries. More precisely, when an instance  $\Pi_{U_i}^s$  has received a message  $(\text{hp}_j, C_j)$  from  $U_j$  and previously received messages  $(\text{hp}_k, C_k)$  from all the other users  $U_k$  with  $k \neq i, j$ , then we choose  $\text{sk}$  at random. The proof is a non-trivial extension of the technical lemma of Katz and Vaikuntanathan in [KV11].

As explained above, we consider a sequence of hybrid games  $\mathbf{G}_{3,h}$ , where  $h$  is a tuple of the form  $(s, i, S)$ , where  $s$  is a session id ( $s \in \{1, \dots, q_{\text{session}}\}$ ),  $i$  is a player id ( $i \in \{1, \dots, n\}$ ), and  $S$  is a strict subset of  $\{1, \dots, n\}$  which does not contains  $i$ . We choose an arbitrary (total) order  $\prec$  over the tuples  $h$  so that if  $h = (s, i, S) \prec h' = (s', i', S')$ , then  $|S| \leq |S'|$ . We also suppose there exists a special  $h = \perp$ , which is less ( $\prec$ ) than all regular  $h$  tuples. Furthermore,  $h - 1$  denotes the tuple  $h$  just before  $h$  in the order  $\prec$ . Note there are  $q_{\text{session}}n2^{n-1} + 1$  tuples  $h = (s, i, S)$ . This number of tuples is much higher than the number of sessions, and the number of hybrid games is exponential on  $n$ , because we do not know in advance the structure of the set  $S$  for the session  $s$ . Hence, we need to enumerate all the possibilities.

We denote by  $\text{hk}_{i,s}$  the hashing key honestly generated by  $\Pi_{U_i}^s$  (supposing wlog. that any instance always generate such hashing key even if it is not asked by the adversary, through a  $\text{Send}_0$  query) and by  $\text{hp}_{i,s}$  the associated projection key (which is sent by  $\Pi_{U_i}^s$ , if asked by the adversary). We also say an hash value we have to compute is of type  $h$ , if it is a hash value under  $\text{hk}_{i,s}$  of ciphertexts  $(C_j)_{j \neq i}$  (with labels  $(\ell_j)_{j \neq i}$ ), where:

- for  $j \in S$ ,  $C_j$  was honestly generated by  $\Pi_{U_j}^s$ ,
- for  $j \notin S$ ,  $C_j$  was generated (altered) by the adversary (and so we know that these ciphertexts  $C_j$  are not valid ciphertexts of  $\text{pw}^*$ ).

Notice there may be up to  $|S| + 1$  hash values of type  $h$ , since  $\Pi_{U_i}^s$  and all the  $\Pi_{U_j}^s$  with  $j \in S$  may need to compute a hash value of type  $h$ . In addition, when  $|S| = n - 1$ , all these hash values are equal. Therefore, we can see there are at most  $n - 1$  distinct hash values of type  $h$ , hence the requirement of a  $(n - 1)$ -smooth SPHF (details follow).

The hybrid  $\mathbf{G}_{3,h}$ , with  $h = (s, i, S)$  is defined as follows: all hash values of types  $\preceq h$  are replaced by random values. Clearly  $\mathbf{G}_{3,\perp}$  is  $\mathbf{G}_2$ , while  $\mathbf{G}_{3,\top}$  is  $\mathbf{G}_3$ , where  $\top$  is the maximal tuple for  $\prec$ .

Let  $h \neq \perp$  be a tuple  $(s, i, S)$ . We now just need to prove that  $\mathbf{G}_{3,h-1}$  is computationally indistinguishable from  $\mathbf{G}_{3,h}$ . This is basically done by the following sequence of sub-hybrid games:

**Game  $\mathbf{G}_{3,0}$ :** This game is  $\mathbf{G}_{3,h-1}$ .

**Game  $\mathbf{G}_{3,1}$ :** Let  $C_{j,s}$  be the ciphertext honestly generated by  $\Pi_{U_j}^s$ , for  $j \in \{1, \dots, n\}$ , and  $\ell_{j,s}$  be the associated label. In this game, for  $j \in S$ , when  $\Pi_{U_j}^s$  wants to compute the hash value of the ciphertext he received under a projection key  $\text{hp}$  from some adversarially generated flow from some  $\Pi_{U_k}^s$ , then:

- either this hash value is of type  $\prec h$ , in which case, it is actually chosen at random,
- or, it is not, in which case, this implies that at least  $|S|$  flows received by  $\Pi_{U_j}^s$  are honestly generated. In the previous game, we would compute the requested hash value using the random coins used in  $C_{j,s}$ , as witness. In this game, we do not want to do that, and instead we remark that among these  $|S|$  honest flows, at least one comes from a  $\Pi_{U_k}^s$  for  $k \notin S$ ; otherwise  $S$  would contain at least  $|S| - 1 + 1$  values, the “+1” coming from the fact  $j \in S$ . Therefore, we can compute the requested hash values using the random coins of  $C_{k,s}$  as witness.

This game is clearly perfectly indistinguishable from the previous one. In addition, in this game, the random coins of  $C_{j,s}$  are never used.

**Game  $\mathbf{G}_{3.2}$ :** In this game, we now generate  $C_{j,s}$  for  $j \in S$ , as a ciphertext of a dummy (invalid) password. This game is indistinguishable from the previous one, we use the IND-CCA property of the encryption scheme (in a classical hybrid way).

**Game  $\mathbf{G}_{3.3}$ :** Now, the  $(n-1)$ -smoothness property of the SPHF ensures that the (at most  $n-1$ ) hash values of type  $h$  look like independent random values, since these hash values are for words outside the language (all the ciphertexts used are either honestly generated for  $C_{j,s}$  for  $j \in S$ , and so containing a dummy password, or adversarially generated, and so not containing the correct password  $\text{pw}^*$ ). So in this game, we now replace all hash values of type  $h$  by independent random values.

**Game  $\mathbf{G}_{3.4}$ :** In this game, we encrypt again  $\text{pw}^*$  in  $C_{j,s}$  (for  $j \in S$ ). This game is computationally indistinguishable from the previous one under the IND-CCA property of the encryption scheme.

**Game  $\mathbf{G}_{3.5}$ :** In this game, we undo what has been done in  $\mathbf{G}_{3.1}$ . This game is perfectly indistinguishable from the previous one. This game is also exactly  $\mathbf{G}_{3,h}$ .

The last hybrid  $\mathbf{G}_{3,\top}$  corresponds to our current game  $\mathbf{G}_3$ , i.e. to the case where all secret keys are computed at random. We proved that this game is indistinguishable from the previous and that:

$$|\text{Adv}_3(\mathcal{A}) - \text{Adv}_2(\mathcal{A})| \leq q_{\text{session}} n 2^{n-1} \cdot \text{negl}(),$$

since there are  $q_{\text{session}} n 2^{n-1} + 1$  hybrids.

**Game  $\mathbf{G}_4$ :** We now modify the way one answers the  $\text{Send}_0$ -queries: instead of encrypting the correct values, we encrypt a dummy password. Under the IND-CCA security of the encryption scheme:  $|\text{Adv}_4(\mathcal{A}) - \text{Adv}_3(\mathcal{A})| \leq \text{negl}()$ .

If there is no event  $\text{EventStop}$  (even  $\neg \text{EventStop}$ ), then this last game looks exactly the same when  $b = 0$  and when  $b = 1$ , hence:

$$\begin{aligned} \text{Adv}_4(\mathcal{A}) &\leq 2(\Pr[b' = b \mid \neg \text{EventStop}] \cdot \Pr[\neg \text{EventStop}] \\ &\quad + \Pr[b' = b \mid \text{EventStop}] \cdot \Pr[\text{EventStop}]) - 1 \\ &\leq 2 \cdot \left( \frac{1}{2} (1 - \Pr[\text{EventStop}]) + \Pr[\text{EventStop}] \right) - 1 \\ &\leq \frac{1}{2} + \Pr[\text{EventStop}]. \end{aligned}$$

Since in  $\mathbf{G}_4$ ,  $\text{pw}^*$  is never used before  $\text{EventStop}$  happens, and since  $\text{EventStop}$  happens when the adversary correctly encrypts  $\text{pw}^*$  (in one of its  $q_{\text{active}}$  active queries), the probability of this event is at most than  $q_{\text{active}}/N$ . In addition, combining all relations above, we also get:

$$\text{Adv}_{\mathcal{A}}^{\text{ake}}(\mathfrak{K}) = \text{Adv}_0(\mathcal{A}) \leq \text{Adv}_4(\mathcal{A}) + q_{\text{session}} n 2^{n-1} \cdot \text{negl}().$$

Therefore, we have:

$$\text{Adv}_{\mathcal{A}}^{\text{ake}}(\mathfrak{K}) \leq \frac{q_{\text{active}}}{N} + q_{\text{session}} n 2^{n-1} \cdot \text{negl}().$$

That concludes the proof, since  $n 2^{n-1} \cdot \text{negl}()$  is negligible in  $\mathfrak{K}$  when  $n$  is logarithmic in  $\mathfrak{K}$ .

### D.3 Trapdoor Smooth Projective Hash Functions

**Definition.** A TSPHF [BBC<sup>+</sup>13] is an extension of a classical SPHF with an additional algorithm  $\text{TSetup}$ , which takes as input the CRS  $\text{crs}$  and outputs an additional CRS  $\text{crs}'$  and a trapdoor  $\mathcal{T}_{\text{crs}'}$  specific to  $\text{crs}'$ , which can be used to compute the hash value of words  $C$  knowing only  $\text{hp}$ . The additional CRS  $\text{crs}'$  is often implicit.

TSPHFs enable to construct efficient PAKE protocols in the UC model and also efficient 2-round zero-knowledge proofs. For the latter, the trapdoor is used to enable the simulator to simulate a prover playing against a dishonest verifier.

Formally, a TSPHF is defined by seven algorithms:

- $\text{TSetup}(\text{crs})$  takes as input the CRS  $\text{crs}$  (generated by  $\text{Setup}_{\text{crs}}$ ) and generates the second CRS  $\text{crs}'$ , together with a trapdoor  $\mathcal{T}_{\text{crs}'}$ ;
- $\text{HashKG}$ ,  $\text{ProjKG}$ ,  $\text{Hash}$ , and  $\text{ProjHash}$  behave as for a classical SPHF;
- $\text{VerHP}(\text{hp}, \text{crs})$  outputs 1 if  $\text{hp}$  is a valid projection key, and 0 otherwise.
- $\text{THash}(\text{hp}, \text{crs}, C, \mathcal{T}_{\text{crs}'})$  outputs the hash value of  $C$  from the projection key  $\text{hp}$  and the trapdoor  $\mathcal{T}_{\text{crs}'}$ .

It must verify the following properties:

- *Correctness* is defined by two properties: *hash correctness*, which corresponds to correctness for classical SPHFs, and an additional property called *trapdoor correctness*, which states that, for any  $C \in \mathcal{X}$ , if  $\text{hk}$  and  $\text{hp}$  are honestly generated, we have:  $\text{VerHP}(\text{hp}, \text{crs}) = 1$  and  $\text{Hash}(\text{hk}, \text{crs}, C) = \text{THash}(\text{hp}, \text{crs}, C, \mathcal{T}_{\text{crs}'})$ , with overwhelming probability;
- *Smoothness* cannot obviously be statistical because of  $\text{THash}$ . That is why smoothness is defined by the experiments  $\text{Exp}^{\text{smooth-}b}$  depicted in Fig. 7. We suppose that testing  $C \in \mathcal{L}_{\text{crs}}$  can be done in polynomial-time using  $\mathcal{T}_{\text{crs}}$ .

```

Expsmooth-b( $\mathcal{A}, \mathfrak{R}$ )
( $\text{crs}, \mathcal{T}_{\text{crs}}$ )  $\stackrel{\$}{\leftarrow}$  Setupcrs( $1^{\mathfrak{R}}$ )
hk  $\stackrel{\$}{\leftarrow}$  HashKG( $\text{crs}$ )
hp  $\leftarrow$  ProjKG( $\text{hk}, \text{crs}$ )
( $C, \text{st}$ )  $\stackrel{\$}{\leftarrow}$   $\mathcal{A}(\text{crs})$ 
if  $b = 0$  or  $C \in \mathcal{L}_{\text{crs}}$  then
     $H \leftarrow$  Hash( $\text{hk}, \text{crs}, C$ )
else
     $H \stackrel{\$}{\leftarrow} \Pi$ 
return  $\mathcal{A}(\text{st}, H)$ 

```

Fig. 7. Experiments  $\text{Exp}^{\text{smooth-}b}$  for computational smoothness of TSPHF

- The  $(t, \varepsilon)$ -*soundness* property says that, given  $\text{crs}$ ,  $\mathcal{T}_{\text{crs}}$  and  $\text{crs}'$ , no adversary running in time at most  $t$  can produce a projection key  $\text{hp}$ , a word  $C$  and valid witness  $w$  such that  $\text{hp}$  is valid (i.e.,  $\text{VerHP}(\text{hp}, \text{crs}) = 1$ ) but

$$\text{THash}(\text{hp}, \text{crs}, C, \mathcal{T}_{\text{crs}'}) \neq \text{ProjHash}(\text{hp}, \text{crs}, C, w),$$

with probability at least  $\varepsilon$ . The perfect soundness states that the property holds for any  $t$  and any  $\varepsilon > 0$ .

It is important to notice that  $\mathcal{T}_{\text{crs}}$  is not an input of  $\text{THash}$  and it is possible to use  $\text{THash}$ , while generating  $\text{crs}$  with an algorithm which cannot output  $\mathcal{T}_{\text{crs}}$  (as soon as the distribution of  $\text{crs}$  output by this algorithm is indistinguishable from the one output by  $\text{Setup}_{\text{crs}}$ , obviously). For example, if  $\mathcal{T}_{\text{crs}}$  contains a decryption key, it is still possible to use the IND-CPA game for the encryption scheme, while making calls to  $\text{THash}$ .  $\mathcal{T}_{\text{crs}}$  is just used in the definition of the computational smoothness and in the proof of this property.

**New Construction.** Let us now show how to construct a TSPHF for any family of languages  $(\mathcal{L}_{1, \text{crs}_1})_{\text{crs}_1}$  such that there exists two diverse vector spaces  $\mathcal{V}_1 = (\mathcal{X}_1, (\mathcal{L}_{1, \text{crs}_1}), \mathfrak{G}_1, n_1, k_1, \Gamma^{(1, \text{crs}_1)}, (\theta_{1, \text{crs}_1}))$  and  $\mathcal{V}_2 = (\mathcal{X}_2, (\mathcal{L}_{2, \text{crs}_2}), \mathfrak{G}_2, n_2, k_2, \Gamma^{(2, \text{crs}_2)}, (\theta_{2, \text{crs}_2}))$  over two multiplicatively-compatible sub-graded ring  $\mathfrak{G}_1$  and  $\mathfrak{G}_2$  of some graded ring  $\mathfrak{G}$ , such that the second diverse vector space corresponds to a hard subset membership language.

This is actually exactly the same requirement as for NIZK from SPHFs in Section 5.1.

Let  $\mathcal{V} = (\mathcal{X}, \mathcal{L}, \mathcal{R}, \mathfrak{G}, n, \Gamma, \theta)$  be the diverse vector space corresponding to the disjunction of the two previous diverse vector spaces. Let  $\text{crs}'$  contains a random word  $C_2 \stackrel{\$}{\leftarrow} \mathcal{L}_2$  and  $\mathcal{T}_{\text{crs}'} = \lambda_2$

be its witness. Then, the algorithms **HashKG** and **ProjKG** are the same as the one for  $\mathcal{V}$ , while the hash value of a word  $C_1 \in \mathcal{X}_1$  is just the hash value of  $(C_1, C_2)$ . This can be computed in three ways:

- **Hash**: using  $\text{hk}$
- **ProjHash**: using a witness  $\lambda_1$  for  $C_1 \in \mathcal{L}_1$  (if  $C_1 \in \mathcal{L}_1$ )
- **THash**: using the witness  $\mathcal{T}_{\text{crs}'} = \lambda_2$  for  $C_2 \in \mathcal{L}_2$ .

The correctness is trivial, and the computational smoothness directly comes from the smoothness of  $\mathcal{V}$  and the hard subset membership problem for  $\mathcal{L}_2$ :  $\text{crs}' = C_2$  is indistinguishable from a word  $\text{crs}' = C_2 \notin \mathcal{L}_2$ , and in this case, the hash value of  $(C_1, C_2)$  is statistically indistinguishable from random, when  $C_1 \notin \mathcal{L}_1$ .

It remains to define correctly **VerHP** to get the perfect soundness property. For that, **VerHP** checks:

$$\gamma^{(1)} \bullet (\text{Id}_{k_1} \otimes \Gamma^{(2)}) \stackrel{?}{=} \gamma^{(2)} \bullet (\Gamma^{(1)} \otimes \text{Id}_{k_2}), \quad (12)$$

where  $\gamma^{(1)} = (\gamma_j)_{j=1}^{n_2 k_1}$  and  $\gamma^{(2)} = (\gamma_j)_{j=n_2 k_1+1}^{n_2 k_1 + n_1 k_2}$ .

Let  $C_1 \in \mathcal{L}_1$ ,  $C_2 \in \mathcal{L}_2$  with  $\lambda_1$  and  $\lambda_2$  such that  $\hat{C}_1 = \Gamma^{(1)} \bullet \lambda_1$  and  $\hat{C}_2 = \Gamma^{(2)} \bullet \lambda_2$ . The hash value computed with **ProjHash** is then:

$$H' = \gamma^{(1)} \bullet (\lambda_1 \otimes \hat{C}_2) = \gamma^{(1)} \bullet ((\text{Id}_{k_1} \bullet \lambda_1) \otimes (\Gamma^{(2)} \bullet \lambda_2)) = \gamma^{(1)} \bullet (\text{Id}_{k_1} \otimes \Gamma^{(2)}) \bullet (\lambda_1 \otimes \lambda_2)$$

while the hash value computed with **THash** is:

$$H'' = \gamma^{(2)} \bullet (\hat{C}_1 \otimes \lambda_2) = \gamma^{(2)} \bullet ((\gamma^{(1)} \bullet \lambda_1) \otimes (\text{Id}_{k_2} \bullet \lambda_2)) \bullet = \gamma^{(2)} \bullet (\Gamma^{(1)} \otimes \text{Id}_{k_2}) \bullet (\lambda_1 \otimes \lambda_2).$$

And so  $H' = H''$  and Eq. (12) is verified, when  $\text{hp}$  is valid.

**Comparison with the Original Construction.** If  $\mathcal{L}_2$  is just the language of DDH tuples (as in Example 1), then we get a TSPHF slightly less efficient than the original construction: the second part of the projection key ( $\gamma^{(2)}$  here and  $\chi$  in [BBC<sup>+</sup>13]) is twice as long. However, the advantage is that our construction works in more cases: it does not require that there is a way to generate a CRS  $\text{crs}$  with a trapdoor  $\mathcal{T}_{\text{crs}}$  enabling to compute the discrete logarithms of elements of  $\Gamma_1$ , but only enabling to check if a word  $C_1$  is in  $\mathcal{L}_1$  or not.

It is interesting to notice that one can obtain the original TSPHF in [BBC<sup>+</sup>13] by simply replacing the second hard membership diverse vector space  $\mathcal{V}_2$  by the canonical PrPHF  $\mathcal{V}_2$  under  $\kappa\text{-Lin}$  in  $\mathbb{G}_2$  in our construction above. Even though this observation does not lead to a performance improvement, it sheds a new light into the way the original TSPHF construction works, namely, that it was just a disjunction of the language  $\mathcal{L}_1$  and a trivial language  $\mathcal{L}_2$ .
