1. Proof for Proposition 5

– **Upper bound analysis:** The most time consuming part of the RLBFGS algorithm is the recursive function GetDirection(.) defined in Section 2.4. In every call of recursion, Eqs. (1)-(3) are performed. The metric used in Eqs. (1) and (3) takes $\mathcal{O}(n^3)$ and $\mathcal{O}(n^2)$ before and after applying the mappings, respectively (cf. Table 1 in main paper). This is because matrix inversion takes $\mathcal{O}(n^3)$ time and the matrices are vectorized within trace operator in the algorithm implementation. The vector transport used in Eq. (2) takes $\mathcal{O}(n^3)$ and $\mathcal{O}(1)$ before and after applying the mappings, respectively (cf. Table 1 in main paper). Recursion in RLBGS is usually done for a constant m number of times (see Ref. Ring and Wirth, 2020). Overall, the complexity of recursion is $\mathcal{O}(mn^3)$ and $\mathcal{O}(mn^2)$, for RLBFGS with and without mappings, respectively.

– **Lower bound analysis:** Computing matrix inversion in the metric before applying our mappings (cf. Table 1 in main paper) takes $\Omega(n^2 \log n)$ (see article [1] referenced below) while metric takes $\Omega(n^2)$ after the mappings. The vector transport takes $\Omega(n^3)$ and $\Omega(1)$ before and after the mappings, respectively. Overall, the complexity of recursion is $\Omega(mn^3)$ and $\Omega(mn^2)$, for RLBFGS with and without mappings, respectively.
[1] A. Tveit, "On the complexity of matrix inversion," Norwegian University of Science and Technology, Trondheim, Technical Report, 2003.

* The first two authors contributed equally to this work.

– **Tight bound analysis:** As the upper bound and lower bound complexities of the every algorithm are equal, we can conclude that the complexity bound is tight. Therefore, RLBFGS has time complexity $\Theta(mn^3)$ and $\Theta(mn^2)$, with and without our mappings, respectively. This shows that our proposed mappings improve the time of optimization. This time improvement shows off better if computation of gradients in Eq. (6) is not dominant in complexity.

2. Simulations for Larger Sample Size and Dimensionality

Tables 2 and 3, in this Supplementary Material, report the average simulation results for large sample size, i.e., $N = 100n^2$. In these tables, exponential map and Taylor approximation for retraction are used, respectively. We also have reported results for large dimensionality $d = 100$ in these two tables.

3. Cost Difference Progress for $N = 10n^2$ Sample Size Simulations

The log-scale cost difference for simulations of $N = 10n^2$ are depicted in Figs. 1 and 2 of this Supplementary Material, for $K = 2$ and $K = 5$, respectively.

4. Cost Difference Progress for $N = 100n^2$ Sample Size Simulations

The log-scale cost difference for simulations of $N = 100n^2$ are depicted in Figs. 3 and 4 of this Supplementary Material, where exponential map and Taylor approximation for retraction are used, respectively.

Table 1: Comparison of average results over ten runs where retraction with Taylor series expansion is used in algorithms and $K \in \{2, 5\}$, $n \in \{2, 10\}$, $N = 10n^2 \in \{40, 1000\}$. The #iters, conv, iter, diff, and std are short for number of iterations, convergence, iteration, difference, and standard deviation, respectively.
